Uniform convergence of hypergeometric series

Raimundas Vidūnas*

Abstract

The considered problem is uniform convergence of sequences of hypergeometric series. We give necessary and sufficient conditions for uniformly dominated convergence of infinite sums of proper bivariate hypergeometric terms. These conditions can be checked algorithmically. Hence the results can be applied in Zeilberger type algorithms for nonterminating hypergeometric series.

1 Introduction

In this paper we study uniform convergence of sequences of hypergeometric series. We consider the sequences $\mathcal{U}(n)=\sum_{k=0}^{\infty}u(n,k)$ of hypergeometric series such that $u(n,k)$ is a proper hypergeometric term in n,k. We assume that the individual series $\mathcal{U}(n)$ are nonterminating for large enough n. The underlying field is the complex numbers.

Recall [AP02] that a bivariate sequence $u(n,k)$ is a *hypergeometric term* if both quotients $u(n+1,k)/u(n,k)$ and $u(n,k+1)/u(n,k)$ can be realized as rational functions of n,k.

A bivariate sequence $u(n,k)$ is a *proper term* if there exist: a non-negative integer p; complex constants ξ,θ; $b_1,\ldots,b_p$; integers $\alpha_1,\ldots,\alpha_p$; $\beta_1,\ldots,\beta_p$; and a polynomial $P(n,k)$ such that

$$u(n,k)=P(n,k)\,\frac{\xi^n\theta^k}{k!}\,(b_1)_{\alpha_1 n+\beta_1 k}\,\cdots\,(b_p)_{\alpha_p n+\beta_p k},\tag{1.1}$$

where $(a)_m$ is the Pochhammer symbol:

$$(a)_m=\begin{cases} a\,(a+1)\cdots(a+m-1), & \text{if } m>0,\\ 1, & \text{if } m=0,\\ 1/(a-1)\,\cdots\,(a-|m|), & \text{if } m<0.\end{cases}\tag{1.2}$$

In general, $(a)_m = \Gamma(a+m)/\Gamma(a)$. To avoid consideration of undefined or terminating series, we assume that:

(I) For those j with $\alpha_j > 0$ or $\beta_j > 0$ we have $b_j \notin \{0, -1, -2, \ldots\}$.

(II) For those j with $\alpha_j < 0$ or $\beta_j < 0$ we have $b_j \notin \{0, 1, 2, \ldots\}$.

In particular, for those j with $\alpha_j \beta_j < 0$ we must have $b_j \notin \mathbb{Z}$. More generally, one may consider proper hypergeometric terms with the Pochhammer symbols in (1.1) replaced by other factorial-type functions, such as the gamma function of linear arguments in n, k with integer coefficients to n, k, or the *nonvanishing rising factorial* [AP02].

A bivariate sequence $u(n,k)$ is *holonomic* if the generating function $\sum_{n,k\geq 0} u(n,k)\, x^n y^k$ and all its partial derivatives generate a finite-dimensional vector space over the field of rational functions in x, y.

Proper terms are hypergeometric and holonomic [AP02, Theorem 3]. Since our coefficient field is algebraically closed, any holonomic hypergeometric term is *conjugate* to a proper term [AP02, Theorem 14], [Hou01]. This means that there are polynomials f_1, f_2, g_1, g_2 in n, k, not identically zero, and a proper term $\widetilde{u}(n,k)$, such that

$$f_1(n,k)\, u(n+1,k) = f_2(n,k)\, u(n,k), \qquad g_1(n,k)\, u(n,k+1) = g_2(n,k)\, u(n,k), \tag{1.3}$$

and these identities hold with u replaced by $\widetilde{u}$ as well.

If a term $u(n,k)$ is holonomic, then it satisfies difference equations (in one or both variables) whose coefficients are dependent only on n [PWZ96, Chapter 4]. If the term $u(n,k)$ is proper, and for any n the sum $\mathcal{U}(n) = \sum_{k=0}^{\infty} u(n,k)$ is terminating, Zeilberger's algorithm gives a recurrence relation with respect to n for $\mathcal{U}(n)$. The crucial step in Zeilberger's algorithm is to derive a recurrence relation

$$L(n)\, u(n,k) = R(n,k+1) - R(n,k), \tag{1.4}$$

where $L(n)$ is a linear difference operator with coefficients in n only, and $R(n,k)$ is a hypergeometric term. The linear recurrence is derived by summing (1.4) over all k; the right hand-side simplifies due to telescoping summation.

When generalizing Zeilberger's algorithm to nonterminating hypergeometric series, one needs to make sure that the series $\mathcal{U}(n) = \sum_{k=0}^{\infty} u(n,k)$ converges uniformly, so to justify manipulation of (1.4). This paper gives criteria to decide uniform convergence of $\mathcal{U}(n)$. In [VK06] these criteria are used for the Zeilberger type algorithms for nonterminating hypergeometric series. Generalization of q-Zeilberger algorithm to nonterminating basic hypergeometric series is considered in [CHM05].

The main result of this paper is the sufficient and necessary conditions for uniformly dominated convergence of sequences $\mathcal{U}(n) = \sum_{k=0}^{\infty} u(n,k)$ of infinite sums of proper hypergeometric terms $u(n,k)$. Uniformly dominated convergence is defined by the Weierstrass M-test; see Lemma 2.1 below.

The main result is presented in Section 6, and proved in Section 8. In Section 7, examples of application of the main result are given. In Section 2, the crucial technical Lemma 2.2 and a few asymptotic expressions for the gamma function are presented. In Section 3 we provide several other intermediate results. In Sections 4 and 5 we specify the form of hypergeometric series under consideration, and define the notation we use. In Section 9 we consider the least straightforward (from computational point of view) part of the main theorem more closely.

2 Basic preliminary results

Throughout the paper, let $\mathbf{Z}_+$ denote the set of non-negative integers. We make the convention that $0^0 = 1$, which is the proper continuous limit of the function $|x|^x$.

As the criterium for uniform convergence of function series, we use the Weierstrass M-test formulated here below. (We apply it with $E = \mathbf{Z}_+$.)

Lemma 2.1 *Let $f_0(x), f_1(x), f_2(x), \ldots$ be a sequence of complex-valued functions on a set E. If there exists a sequence $M_0, M_1, M_2, \ldots$ of real constants such that $|f_j(x)| \le M_j$ for any $x \in E$ and all $j \in \mathbf{Z}_+$, and the series $\sum_{j=0}^{\infty} M_j$ converges, then the function series $\sum_{j=0}^{\infty} f_j(x)$ converges uniformly on E.*

We refer to a function series that satisfies the sufficient condition of this criterium as a *uniformly dominated convergent* series. In plain terms, the condition is that the series is uniformly bounded (or majorized) by an absolutely convergent series.

The following lemma gives us a strategy to determine uniformly dominated convergence of sequences of nonterminating hypergeometric series.

Lemma 2.2 *Let $u(n,k)$ denote a hypergeometric term in n,k. We assume that the hypergeometric series $\mathcal{U}(n) = \sum_{k=0}^{\infty} u(n,k)$ is nonterminating for large enough n. The series sequence $\mathcal{U}(n)$ is uniformly dominated convergent if and only if the following conditions hold:*

(a) For any $n \ge 0$, the series $\mathcal{U}(n)$ converges absolutely.

(b) The termwise limit $\sum_{k=0}^{\infty} \lim_{n\to\infty} u(n,k)$ exists and converges absolutely.

(c) For any function $N : \mathbf{Z}_+ \to \mathbf{Z}_+$ such that $N(k) \sim C_0\, k^p$ for some real $p > 1$ and $C_0 \neq 0$, the series $\sum_{k=0}^{\infty} u(N(k),k)$ converges absolutely.

(d) *For any function* $N : \mathbf{Z}_+ \to \mathbf{Z}_+$ *such that* $N(k) \sim C_0\, k^p$ *for some real* $p \in (0,1)$ *and* $C_0 \neq 0$, *the series* $\sum_{k=0}^{\infty} u(N(k),k)$ *converges absolutely.*

(e) *For any function* $N : \mathbf{Z}_+ \to \mathbf{Z}_+$ *such that* $N(k) = \lambda\, k + \omega(k)$ *for some real* $\lambda > 0$, *with either* $\omega(k) = O(1)$ *or* $\omega(k) \sim C_0\, k^p$ *for some real* $p \in (0,1)$, $C_0 \neq 0$, *the series* $\sum_{k=0}^{\infty} u(N(k),k)$ *converges absolutely.*

Proof. The conditions are necessary because a uniformly bounding series would be a majorant for the indicated series as well. The limit in *(b)* exists because, for each k, $|u(n,k)|$ is a monotonic function of n for n large enough.

To prove the sufficiency, we may assume that for k large enough $u(n,k)$ is not a constant in n. Let $z(k) = \sup_{n\geq 0} |u(n,k)|$. Then the series $\sum_{k=0}^{\infty} z(k)$ is a precise uniform majorant for $\mathcal{U}(n)$. The series sequence $\mathcal{U}(n)$ is uniformly dominated convergent if and only if the series $\sum_{k=0}^{\infty} z(k)$ converges.

Let $h(\nu,\kappa)$ be the rational function of two complex variables equal to $u(\nu+1,\kappa)/u(\nu,\kappa)$ for positive integer values of ν and κ. Note that $h(\nu,\kappa)$ is nonzero and well defined for positive integers κ and large enough integers ν, because $u(n,k)=0$ would imply that the hypergeometric series are terminating or undefined for large enough n. The function $h(\nu,\kappa)$ may be complex-valued, but the variables ν,κ are assumed to be real.

For each non-negative integer k, we have that either $z(k) = \lim_{n\to\infty} |u(n,k)|$, or

$$z(k) = |u(n_0,k)| \text{ and } |h(n_0,k)| \leq 1,\ |h(n_0-1,k)| \geq 1 \text{ for some integer } n_0.$$

In the latter case, the rational function $|h(\nu,k)|^2$ of ν (with k fixed) has either a pole on the interval $\nu \in [n_0-1, n_0]$, or it is continuous and therefore achieves the value 1 on the same interval.

Let $\widehat{h}(\nu,\kappa)$ be the denominator of $|h(\nu,\kappa)|^2$. Since the series $\mathcal{U}(n)$ are not constant when n large enough, we have that $|h(\nu,k)|$ is not a constant function of ν for all large enough k. Let $\nu_1(\kappa),\ldots,\nu_m(\kappa)$ be the positive real algebraic functions, which are solutions of the algebraic equations $|h(\nu,\kappa)| = 1$ or $\widehat{h}(\nu,\kappa) = 0$, and are defined for large enough κ. For $j = 1,\ldots,m$, let $N_j(k)$ be the integer-valued function

$$N_j(k) = \begin{cases} \lfloor \nu_j(k) \rfloor, & \text{if } |h(\lfloor \nu_j(k) \rfloor, k)| \leq 1, \\ \lceil \nu_j(k) \rceil, & \text{if } |h(\lfloor \nu_j(k) \rfloor, k)| > 1. \end{cases}$$

All these functions satisfy the assumption of one of the last three conditions. The functions $N_j(k)$ give candidates for "local" maximums of $|u(n,k)|$, as n varies over the discrete set of positive integers and k is fixed.

For large enough k, the candidates for $z(k)$ are $|u(0,k)|$, $\lim_{n\to\infty}|u(n,k)|$, and $|u(N_j(k),k)|$ for $j=1,\ldots,m$. Note that each $N_j(k)$ is either bounded and we can apply condition *(a)*, or we can apply one of the conditions *(c)–(e)*. The sum of all candidates gives a series which is a uniform majorant for $\mathcal{U}(n)$. QED.

We will use the following asymptotic expressions for the gamma function. It will be convenient for us to uniformize all gamma expressions with a linear argument in $m\to\infty$ to expressions involving only $\Gamma(m)$. Some corollaries are formulated in less generality than possible, for readiness of application.

Lemma 2.3 *Let λ be a real number, and let $\ell\in\mathbb{C}$.*

- *If $\lambda>0$ then*

$$\Gamma(\lambda\,m+\ell)\sim(2\pi)^{\frac{1-\lambda}{2}}\,\lambda^{\ell-1/2}\,m^{\ell+\frac{\lambda-1}{2}}\,\lambda^{\lambda\,m}\,\Gamma(m)^{\lambda}\qquad\textit{as real } m\to\infty. \tag{2.1}$$

- *If $\lambda<0$, $\ell\notin\mathbb{Z}$, and m runs through a set of real numbers such that $\lambda\,m\in\mathbb{Z}$, then*

$$\Gamma(\lambda\,m+\ell)\sim\frac{(2\pi)^{\frac{1-\lambda}{2}}\,|\lambda|^{\ell-1/2}}{2\,\sin(\pi\ell)}\,m^{\ell+\frac{\lambda-1}{2}}\,\lambda^{\lambda\,m}\,\Gamma(m)^{\lambda}\qquad\textit{as } m\to\infty. \tag{2.2}$$

Proof. The first statement follows from Stirling's asymptotic formula [AAR99, Theorem 1.4.1]:

$$\begin{aligned}\frac{\Gamma(\lambda\,m+\ell)}{\Gamma(m)^{\lambda}} &\sim \frac{\sqrt{2\pi}\,(\lambda m+\ell)^{\lambda\,m+\ell-1/2}\,\exp(-\lambda\,m-\ell)}{(2\pi)^{\lambda/2}\,m^{\lambda\,m-\lambda/2}\,\exp(-\lambda\,m)}\\ &\sim (2\pi)^{\frac{1-\lambda}{2}}\,\lambda^{\lambda\,m+\ell-1/2}\,m^{\ell+\frac{\lambda-1}{2}}\left(1+\frac{\ell}{\lambda\,m}\right)^{\ell-1/2}\left(1+\frac{\ell}{\lambda\,m}\right)^{\lambda\,m}\exp(-\ell).\end{aligned}$$

Note that

$$\lim_{m\to\infty}\left(1+\frac{\ell}{\lambda\,m}\right)^{\ell-1/2}=1\qquad\text{and}\qquad\lim_{m\to\infty}\left(1+\frac{\ell}{\lambda\,m}\right)^{\lambda\,m}=\exp(\ell).$$

Formula (2.1) follows.

To prove the second statement we use Euler's reflection formula [AAR99, Theorem 1.2.1]:

$$\Gamma(\lambda\,m+\ell)=\frac{(-1)^{\lambda m}\,\pi}{\sin\pi\ell}\,\frac{1}{\Gamma\left(|\lambda|m+1-\ell\right)}. \tag{2.3}$$

Now we apply the first statement to $\Gamma\left(|\lambda|m+1-\ell\right)$ and obtain (2.2). QED.

Corollary 2.4 *Let λ be a nonzero real number, and let $\ell \in \mathbb{C}$. We assume that m runs through a set of real numbers such that λm is an integer. If $\lambda < 0$ then we additionally assume that $\ell \notin \mathbb{Z}$. Under these assumptions there is a constant $C_0 \in \mathbb{C}$ such that*

$$\Gamma(\lambda\, m + \ell) \;\sim\; C_0\, m^{\ell+\frac{\lambda-1}{2}}\, \lambda^{\lambda m}\, \Gamma(m)^{\lambda} \tag{2.4}$$

as $m \to \infty$.

Corollary 2.5 *Let λ, N be integers, and let $\ell \in \mathbb{C}$. We assume that $\lambda \neq 0$. If $\lambda < 0$ we additionally assume that $\ell \notin \mathbb{Z}$. Then, as integer $m \to \infty$,*

$$\Gamma(\lambda\, m + N + \ell) \;\sim\; C_0\, (2\pi)^{\frac{1-\lambda}{2}}\, |\lambda|^{\ell-1/2}\, \lambda^{N}\, m^{N+\ell+\frac{\lambda-1}{2}}\, \lambda^{\lambda m}\, \Gamma(m)^{\lambda}, \tag{2.5}$$

where

$$C_0 = \begin{cases} 1, & \text{if } \lambda > 0, \\ \frac{1}{2\sin \pi\ell}, & \text{if } \lambda < 0. \end{cases} \tag{2.6}$$

Proof. For $\lambda < 0$, the simplification is $|\lambda|^N / \sin \pi(\ell + N) = \lambda^N / \sin \pi\ell$. QED.

3 Other preliminary results

Here we continue with more asymptotic formulas for the gamma function and Pochhammer symbols. Lemma 3.7 is used only in the auxiliary Section 9.

We introduce the following function:

$$\Theta(x) = \frac{1+x}{x}\, \log(1+x) - 1. \tag{3.1}$$

Lemma 3.1 *Let $\omega(m)$ denote a real-valued function defined for large enough $m \in \mathbb{R}$, such that $\omega(m) = o(m)$ as $m \to \infty$. Then*

$$\Gamma(m + \omega(m)) \sim m^{\omega(m)}\, \exp\left(\omega(m)\, \Theta\!\left(\frac{\omega(m)}{m}\right)\right) \Gamma(m) \qquad \text{as} \quad m \to \infty. \tag{3.2}$$

Proof. By Stirling's asymptotic formula:

$$\begin{aligned}\frac{\Gamma(m+\omega(m))}{\Gamma(m)} &\sim \frac{(m+\omega(m))^{m+\omega(m)-1/2}}{m^{m-1/2}}\,\exp(-\omega(m))\\ &\sim m^{\omega(m)}\left(1+\frac{\omega(m)}{m}\right)^{m+\omega(m)-1/2}\exp(-\omega(m))\\ &\sim m^{\omega(m)}\,\exp\left((m+\omega(m))\,\log\left(1+\frac{\omega(m)}{m}\right)-\omega(m)\right). \end{aligned}\tag{3.3}$$

The result follows. QED.

Corollary 3.2 *Let $\omega(m)$ denote a real-valued function defined for large enough $m \in \mathbb{R}$, such that $\omega(m) = o(m)$ as $m \to \infty$. Then*

$$\Gamma(m+\omega(m)) \sim m^{\omega(m)}\,\exp\left(\sum_{j=1}^{\infty}\frac{(-1)^{j+1}}{j\,(j+1)}\,\frac{\omega(m)^{j+1}}{m^j}\right)\,\Gamma(m). \tag{3.4}$$

Proof. On the interval $x \in (-1,1)$ we have

$$\Theta(x) = \sum_{j=1}^{\infty}\frac{(-1)^{j+1}}{j\,(j+1)}\,x^j. \tag{3.5}$$

QED.

As a direct consequence, we obtain the following well known asymptotics:

$$(\ell)_m = \frac{\Gamma(m+\ell)}{\Gamma(m)} \sim m^{\ell}, \qquad \text{as} \quad m \to \infty \qquad (\ell \in \mathbb{C}). \tag{3.6}$$

Lemma 3.3 *Let λ be a nonzero real number, and let $\ell \in \mathbb{C}$. If $\lambda < 0$ we additionally assume that $\ell \notin \mathbb{Z}$. Let $N = N(m)$ denote a function $N : \mathbf{Z}_+ \to \mathbf{Z}_+$ such that $N(m) - \lambda\, m = o(m)$ as $m \to \infty$. Let $\omega(m)$ denote the difference $N(m) - \lambda\, m$. Then there is a constant $C_1 \in \mathbb{C}$ such that*

$$(\ell)_{N(m)} \sim C_1\, m^{\ell+\frac{\lambda-1}{2}}\,\lambda^{N(m)}\,m^{\omega(m)}\,\exp\left(\omega(m)\,\Theta\!\left(\frac{\omega(m)}{\lambda\, m}\right)\right)\Gamma(m)^{\lambda} \qquad \text{as} \quad m \to \infty. \tag{3.7}$$

Proof. We have $N(m) = \lambda\, m + \omega(m)$ and $(\ell)_N = \Gamma(N+\ell)/\Gamma(\ell)$. Applying Corollary 2.4,

$$\begin{aligned}\Gamma(\lambda\, m + \omega(m) + \ell) &= \Gamma\left(\lambda\left(m + \frac{\omega(m)}{\lambda}\right) + \ell\right)\\ &\sim C_0\, m^{\ell+(\lambda-1)/2}\, \lambda^{\lambda\, m+\omega(m)}\, \Gamma\left(m + \frac{\omega(m)}{\lambda}\right)^{\lambda}.\end{aligned}$$

Then we apply Lemma 3.1 to the last factor. QED.

Corollary 3.4 *Let λ be a nonzero integer, and let $\ell \in \mathbb{C}$. If $\lambda < 0$, we assume that $\ell \notin \mathbb{Z}$. Let $\omega(m)$ denote a function $\omega : \mathbf{Z}_+ \to \mathbf{Z}_+$ such that $\omega(m) = o(m)$ as $m \to \infty$. Then there is a constant $C_0 \in \mathbb{C}$ such that*

$$(\lambda\, m + \ell)_{\omega(m)} \sim C_0\, \lambda^{\omega(m)}\, m^{\omega(m)} \exp\left(\omega(m)\, \Theta\!\left(\frac{\omega(m)}{\lambda\, m}\right)\right) \qquad \textit{as} \quad m \to \infty. \tag{3.8}$$

Proof. We have $(\lambda\, m + \ell)_{\omega(m)} = \Gamma(\lambda\, m + \omega(m) + \ell)/\Gamma(\lambda\, m + \ell)$. Lemma 3.3 can be applied to the numerator and the denominator. QED.

Lemma 3.5 *Let λ be a nonzero integer, and let $\ell \in \mathbb{C} \setminus \mathbb{Z}$. Let $\omega(m)$ denote a function $\omega : \mathbf{Z}_+ \to \mathbb{R}$ such that $\lambda\, \omega(m) \in \mathbb{Z}$ whenever $m \in \mathbb{Z}_+$.*

- *If $\omega(m)$ is bounded as m varies over $\mathbb{Z}_+$, then the Pochhammer symbol $(\ell)_{\lambda\, \omega(m)}$ is bounded, and it is bounded away from zero as well.*
- *Suppose that $\omega(m)$ approaches $+\infty$ or $-\infty$ as $m \to \infty$. Let us denote*

  $$\varepsilon = \begin{cases} \;\;1, & \textit{if } \omega(m) \to +\infty \textit{ as } m \to \infty,\\ -1, & \textit{if } \omega(m) \to -\infty \textit{ as } m \to \infty,\end{cases} \tag{3.9}$$

  Then there is a constant $C_0 \in \mathbb{C}$ such that

  $$(\ell)_{\lambda\, \omega(m)} \sim C_0\, |\omega(m)|^{\ell-\frac{1}{2}+\frac{1}{2}\varepsilon\lambda}\, (\varepsilon\lambda)^{\lambda\, \omega(m)}\, \Gamma(|\omega(m)|)^{\varepsilon\lambda}. \tag{3.10}$$

Proof. If $\omega(m)$ is bounded, $\lambda\omega(m)$ achieves finitely many values. The same holds for the Pochhammer symbol. Since $\ell \notin \mathbb{Z}$, the Pochhammer symbol is never zero.

If $\omega(m) \to +\infty$, by Corollary 2.4 we have

$$\Gamma(\lambda\, \omega(m) + \ell) \sim \widetilde{C}_0\, \omega(m)^{\ell+\frac{\lambda-1}{2}}\, \lambda^{\lambda\, \omega(m)}\, \Gamma(\omega(m))^{\lambda}.$$

If $\omega(m) \to -\infty$, we apply Corollary 2.4 to $\Gamma(-\lambda\,|\omega(m)| + \ell)$. The result is

$$\Gamma(\lambda\,\omega(m) + \ell) \sim \widehat{C}_0\,|\omega(m)|^{\ell - \frac{\lambda+1}{2}}\,(-\lambda)^{\lambda\,\omega(m)}\,\Gamma(|\omega(m)|)^{-\lambda}.$$

The Pochhammer symbol grows accordingly. QED.

Lemma 3.6 *Let* $Z = \sum_{j=0}^{\infty} v_j$ *be a series,* ϱ *be a positive real number, and let*

$$w(j) = \frac{\log|v_j|}{j^\varrho} \qquad \textit{for} \quad j = 1, 2, \ldots.$$

- *If* $\lim_{j\to\infty} w(j) = -\infty$ *or* $\lim_{j\to\infty}\sup w(j) < 0$*, then the series* Z *converges absolutely.*
- *If* $\lim_{j\to\infty}\sup w(j) = \infty$ *or* $\lim_{j\to\infty}\sup w(j) > 0$*, then the series* Z *diverges.*

Proof. The case $\varrho = 1$ is equivalent to the standard convergence criteria involving $\lim\sup|v_j|^{1/j}$; see [Rud74]. To prove the first statement in general, we choose a positive real number K such that $w(j) < -K$ for large enough j. Then $\log|v_j| < -Kj^\varrho < -2\log j$ for large enough j. Therefore a tail of the series Z can be majorated by $\sum j^{-2}$, so converges absolutely.

To prove the second statement we choose a positive real K such that $w(j) > K$ for arbitrary large j. Then $\log|v_j| > Kj^\varrho$, so v_j is unbounded. Hence the series Z diverges. QED.

Lemma 3.7 *Let* a, b, p *be real numbers. Assume that* $a > 0$ *and* $0 < p < 1$*. Consider the sequence* $v_j = (aj + b)\,p^j$*, with* $j = 0, 1, 2, \ldots$*. Then*

$$v_{j+1} < v_j \qquad \textit{if} \qquad j > \frac{p}{1-p} - \frac{b}{a}.$$

Proof. A straightforward computation. QED.

4 Notation

We work with a proper hypergeometric term presented in (1.1):

$$u(n,k) = P(n,k)\,\frac{\xi^n\theta^k}{k!}\,(b_1)_{\alpha_1 n + \beta_1 k}\,\cdots\,(b_p)_{\alpha_p n + \beta_p k}. \tag{4.1}$$

We assume the conditions *(I)–(II)* presented after formula (1.1). Then the series $\mathcal{U}(n) = \sum_{k=0}^{\infty} u(n,k)$ is well defined[1] for all non-negative integers n, and it is nonterminating for all but possibly finitely many non-negative integers n. Note that we allow $P(n,k) = 0$ for infinitely many integer pairs (n,k). In particular, $P(n,k)$ may have linear factors in n, k.

Now we introduce a lot of notation for the expressions we need to check in order to determine uniformly dominated convergence for the series $\mathcal{U}(n)$. Example 4.5 below should be a helpful guide[2] and motivator.

For those j with $\beta_j \neq 0$ we introduce

$$\widehat{a}_j = b_j + \frac{\beta_j - 1}{2}. \tag{4.2}$$

For those j with $\alpha_j \neq 0$ we set

$$\widetilde{a}_j = b_j + \frac{\alpha_j - 1}{2}. \tag{4.3}$$

Let us also introduce the following notation:

$$D_0 = -1 + \sum_{j=1}^{p} \beta_j, \qquad D_1 = \sum_{\alpha_j \neq 0} \beta_j, \qquad D_0^* = \sum_{j=1}^{p} \alpha_j, \qquad D_1^* = \sum_{\beta_j \neq 0} \alpha_j. \tag{4.4}$$

---

[1] Slightly more generally, one may consider proper terms with the Pocchammer symbols $(b_j)_{\alpha_j n + \beta_j k}$ replaced by $(b_j + \alpha_j\, n)_{\beta_j\, k}$, and insist on conditions *(I)* and *(II)* only when $\beta_j > 0$, $\alpha_j \le 0$ respectively $\beta_j < 0$, $\alpha_j \ge 0$. Then the series $\sum_k u(n,k)$ would be well defined and nonterminating for large enough n. Our results can be easily applied to this form as well, since we can always identify $(b_j + \alpha_j\, n)_{\beta_j k} = (b_j)_{\alpha_j n + \beta_j k}/(b_j)_{\alpha_j n}$ for large enough n. Example 4.5 below employs reminiscent form.

A customary alternative is to write a general proper hypergeometric term in the form

$$u(n,k) = P(n,k)\, \frac{(b_1)_{\alpha_1 n + \beta_1 k} \cdots (b_p)_{\alpha_p n + \beta_p k}}{(d_1)_{\gamma_1 n + \delta_1 k} \cdots (d_q)_{\gamma_q n + \delta_q k}\, k!}\, \xi^n \theta^k,$$

where we would require $\beta_j \ge 0$ (and perhaps $\alpha_j > 0$ if $\beta_j = 0$) and $\delta_j \ge 0$ (and perhaps $\gamma_j > 0$ if $\delta_j = 0$). Then notation definitions and formulas in the proof become slightly more complicated. The first electronic version of this article was written for this customary form.

[2] As an extra guidance to our notation, we indicate that most conditions for uniformly dominant convergence of $\mathcal{U}(n)$ come from convergence conditions of several series of the following asymptotic form:

$$\sim \Gamma(k)^{D_0}\, \Gamma(n)^{D_0^*}\, z_1^k\, \zeta_0^n\, k^{A_0 - 1}\, n^{A_\infty^*}\, \exp\!\left(k\, \Phi_\infty\!\left(\frac{k}{n}\right)\right).$$

The variables in (4.4) appear in the powers of $\Gamma(k)$ and $\Gamma(n)$ in these asymptotic forms; the expressions in (4.5)–(4.9), (4.13)–(4.14) and (4.19) appear in the powers of k and n; the expressions in (5.1)–(5.3) appear with the exponents of k and n; the functions in (5.13)–(5.15) appear in the additional exponent.

In the sums for D_1 and D_1^*, the summation range is understood to be over all j for which $\alpha_j \neq 0$ respectively $\beta_j \neq 0$. In the rest of the paper, summation or product ranges are implied by the range of definition of involved variables and by indicated conditions. For example, $\sum_{\alpha_j=0} \widehat{a}_j$ is a summation over those j for which $\beta_j > 0$ and $\alpha_j = 0$. With this convention we define:

$$\begin{aligned}
A_0 &= \sum \widehat{a}_j + \deg_k P(n,k), && (4.5)\\
A_\infty^* &= \sum \widetilde{a}_j + \deg_n P(n,k), && (4.6)\\
A_0^* &= \sum_{\alpha_j=0} \widehat{a}_j + \deg_k Q(k), && (4.7)\\
A_1 &= \sum \widehat{a}_j + \sum_{\beta_j=0} \widetilde{a}_j + \deg_{\{n,k\}} P(n,k), && (4.8)\\
A_1^* &= \sum_{\alpha_j=0} \widehat{a}_j + \sum \widetilde{a}_j + \deg_{\{n,k\}} P(n,k). && (4.9)
\end{aligned}$$

In (4.7), we denote

$$Q(k) := \text{the leading coefficient of } P(n,k) \text{ with respect to } n. \tag{4.10}$$

Thus $Q(k)$ is a polynomial in k.

Now we define the function

$$\varphi(p) = \max_{\substack{f:\,\text{a monomial}\\ \text{of } P(n,k)}} \left(\deg_k f + p \deg_n f\right). \tag{4.11}$$

Therefore $\varphi(p)$ is the degree of the polynomial $P(n,k)$ if we give the weight 1 to the variable k and the weight $p > 0$ to the variable n. We have the following properties.

Lemma 4.1 *(i) For a function $N(k) : \mathbb{Z}_+ \to \mathbb{R}$ such that $N(k) \sim C_0\, k^p$ as $k \to \infty$ for some nonzero constant C_0 and real $p > 0$, we have $P(N,k) = O(k^{\varphi(p)})$. For a general such function $N(k)$, there is a nonzero constant C_1 such that $P(N,k) \sim C_1\, k^{\varphi(p)}$.*

(ii) The function $\varphi(p)$ is a continuous piecewise linear function on the real interval $[0,\infty)$, monotone nondecreasing. The linear slope of $\varphi(p)$ can only increase as p increases, as well.

(iii) For large enough p, we have $\varphi(p) = p \deg_n P(n,k) + \deg_k Q(k)$.

Proof. The first part is clear. In particular, for any fixed $p > 0$ the second statement holds for general C_0.

Let $\mathbf{P}$ denote the Newton polygon of $P(n,k)$, that is, the convex hull in $\mathbb{R}^2$ of all half-lines from (U,V) to $(U,-\infty)$ and $(-\infty,V)$ for each monomial $k^U n^V$ of $P(n,k)$. Let $\{(U_i,V_i)\}_{i=1}^m$ be the sequence of the vertices of $\mathbf{P}$, ordered by increasing V_i. Then

$$\varphi(p) = \begin{cases} V_1 p + U_1, & \text{if } 0 \le p \le \frac{U_1-U_2}{V_2-V_1}, \\ V_i\, p + U_i, & \text{for } 1 < i < m \text{ and } \frac{U_{i-1}-U_i}{V_i-V_{i-1}} \le p \le \frac{U_i-U_{i+1}}{V_{i+1}-V_i}, \\ V_m p + U_m, & \text{if } p \ge \frac{U_{m-1}-U_m}{V_m-V_{m-1}}. \end{cases} \tag{4.12}$$

The last two claims follow. QED.

Consequently, we introduce the two functions:

$$\psi_0(p) \;=\; \sum \widehat{a}_j + p \sum_{\beta_j=0} \widetilde{a}_j + \varphi(p), \tag{4.13}$$

$$\psi_\infty(p) \;=\; \sum_{\alpha_j=0} \widehat{a}_j + p \sum \widetilde{a}_j + \varphi(p). \tag{4.14}$$

We will consider $\psi_0(p)$ on the interval $[0,1]$, and the function $\psi_\infty(p)$ on the interval $[1,\infty)$. We have the following properties.

Lemma 4.2 *(i) The real parts of $\psi_0(p)$ and $\psi_\infty(p)$ are continuous piecewise linear functions on the real interval $[0,\infty)$. Their linear slopes can only increase as p increases.*

(ii) On any interval $[U,V] \subset [0,\infty)$, the real parts of $\psi_0(p)$ and $\psi_\infty(p)$ achieve their maximum on $[U,V]$ at an end point, U or V.

(iii) Let (U,V) be a subinterval $[0,\infty)$, so possibly $V=\infty$. If the linear slope of Re $\psi_0(p)$ *or* Re $\psi_\infty(p)$ *is zero or negative as $p \to V$ from the left, then the supremum of* Re $\psi_0(p)$ *or* Re $\psi_\infty(p)$ *on (U,V) is approached as $p \to U$.*

(iv) $\psi_0(0) = A_0$, $\psi_0(1) = A_1$, and $\psi_\infty(1) = A_1^*$.

(v) For large enough p, we have $\psi_\infty(p) = p\, A_\infty^* + A_0^*$.

Proof. The first part follows from Lemma 4.1 *(ii)*. Since the slopes can only increase, on each interval $[U,V]$ the real parts of $\psi_0(p)$ and $\psi_\infty(p)$ are either monotone functions, or there is one locally extremal value inside the interval and that value is a local minimum. This shows the second part. In part *(iii)*, the function Re $\psi_0(p)$ or Re $\psi_\infty(p)$ does not increase on (U,V). The last two parts are straightforward. QED.

Let us define the set

$$\Omega = \left\{ -\frac{\beta_j}{\alpha_j} \right\}_{\alpha_j \neq 0}, \tag{4.15}$$

and the family of polynomials

$$P^\star_\lambda(n,k) := P(\lambda k + n, k). \tag{4.16}$$

We assume that the polynomial $P^\star_\lambda(n,k)$ is expanded whenever we implicitly use it for some λ. Similarly as in (4.11), we define the family of functions

$$\varphi^\star_\lambda(p) = \max_{\substack{f\text{: a monomial}\\ \text{of } P^\star_\lambda(n,k)}} \left(\deg_k f + p \deg_n f \right). \tag{4.17}$$

We may need to consider these functions on the interval $p \in [0,1]$.

Lemma 4.3 *(i) We have $\varphi^\star_\lambda(1) = \varphi(1)$, and $\varphi^\star_\lambda(p) \le \varphi(1)$ for $p \in [0,1]$. If*

$$\deg_k P(\lambda\, k, k) = \deg_{\{n,k\}} P(n,k), \tag{4.18}$$

then $\varphi^\star_\lambda(p) = \varphi(1)$ for any $p \in [0,1]$.

(ii) The function $\varphi^\star_\lambda(p)$ is a continuous piecewise linear function on the real interval $[0,1]$, monotone nondecreasing. The linear slope of $\varphi^\star_\lambda(p)$ can only increase as p increases, as well.

(iii) Let $N(k) : \mathbb{Z}_+ \to \mathbb{R}$ denote a function such that $N(k) \sim \lambda\, k + C_0\, k^p$ as $k \to \infty$ for some nonzero constants $C_0 \neq 0$, $\lambda \neq 0$ and $p \in [0,1)$. Then $P(N,k) \sim C_1 k^{\varphi^\star_\lambda(p)}$ for some nonzero constant C_1.

Proof. For the first part, note that $\deg_{\{n,k\}} P^\star_\lambda(\lambda\, k, k) = \deg_{\{n,k\}} P(n,k)$. If (4.18) is satisfied, then the coefficient of $P^\star_\lambda(n,k)$ to $k^{\varphi(1)}$ is nonzero. (Non-generically, we may have $\deg_k P(\lambda\, k, k) < \deg_{\{n,k\}} P(n,k)$.)

The other two parts follow similarly as parts *(ii)* and *(i)* of Lemma 4.1, respectively. QED.

We introduce a variation of $\psi_0(p)$ as well:

$$\psi^\star_\lambda(p) = \sum_{\alpha_j\lambda+\beta_j\neq 0} \left(\widehat{a}_j + \frac{\alpha_j}{2} \right) + \sum_{\beta_j=0} \widetilde{a}_j + p \sum_{\alpha_j\lambda+\beta_j=0} \widehat{a}_j + \varphi^\star_\lambda(p). \tag{4.19}$$

Note that the linear coefficient to p is zero if $\lambda \notin \Omega$.

Lemma 4.4 *(i) For generic λ, the function $\psi^\star_\lambda(p)$ is a constant:*

$$\psi^\star_\lambda(p) = A_1 + \frac{D_1^*}{2} \; = \; A_1^* + \frac{D_1}{2}. \tag{4.20}$$

(ii) For any λ, the real part of $\psi^\star_\lambda(p)$ is a continuous piecewise linear function on the real interval $[0,1]$. Its linear slope can only increase as p increases.

(iii) On any interval $[U,V] \subset [0,1]$, the real part of $\psi^\star_\lambda(p)$ achieve its maximum on $[U,V]$ at an end point, U or V. If the linear slope of $\mathrm{Re}\ \psi^\star_\lambda(p)$ is zero or negative as $p \to V$ from the left, then the supremum of $\mathrm{Re}\ \psi^\star_\lambda(p)$ on (U,V) is approached as $p \to U$.

Proof. In the first part, the generic λ are those $\lambda \not\in \Omega$ which satisfy (4.18). Other two parts follow similarly as parts *(i)–(iii)* of Lemma 4.2. QED.

Example 4.5 Consider the hypergeometric series

$${}_s\mathrm{F}_r\left(\left. \begin{array}{c} b_1+\alpha_1 n,\, \ldots,\, b_S+\alpha_S n,\, b_{S+1},\ldots,b_s \\ d_1+\gamma_1 n,\, \ldots,\, d_R+\gamma_R n,\, d_{R+1},\ldots,d_r \end{array} \right| Z \right), \tag{4.21}$$

where α_i's and γ_i's are nonzero integers. To put the hypergeometric series in the form (4.1), we may rewrite it as

$$\sum_{k=0}^{\infty} \prod_{j=1}^{S} \frac{(b_j)_{\alpha_j n+k}}{(b_j)_{\alpha_j n}} \prod_{j=1}^{R} \frac{(d_j)_{\gamma_j n}}{(d_j)_{\gamma_j n+k}} \frac{\prod_{j=S+1}^{s}(b_j)_k}{\prod_{j=R+1}^{r}(d_j)_k} \frac{Z^k}{k!},$$

and then move the Pochhammer symbols in the denominators by using

$$\frac{1}{(b_j)_{\alpha_j n}} = (1-b_j)_{-\alpha_j n}(-1)^{\alpha_j n}, \quad \frac{1}{(d_j)_{\gamma_j n+k}} = (1-d_j)_{-\gamma_j n-k}(-1)^{\gamma_j n+k}, \quad \text{etc.}$$

In the setting of (4.2) and (4.3), the set of all $\widehat{a}_j$'s is

$$\{b_j\}_{j=1}^{s} \cup \{-d_j\}_{j=1}^{r},$$

and the set of all $\widetilde{a}_j$'s is

$$\left\{b_j + \tfrac{\alpha_j-1}{2}\right\}_{j=1}^{S} \cup \left\{-b_j + \tfrac{1-\alpha_j}{2}\right\}_{j=1}^{S} \cup \left\{d_j + \tfrac{\gamma_j-1}{2}\right\}_{j=1}^{R} \cup \left\{-d_j + \tfrac{1-\gamma_j}{2}\right\}_{j=1}^{R}.$$

We have:

$$D_0 = s - r - 1, \qquad D_0^* = 0, \qquad D_1 = S - R, \qquad D_1^* = \sum_{j=1}^{S} \alpha_j - \sum_{j=1}^{R} \gamma_j, \tag{4.22}$$

$$A_0^* = A_1^* = \sum_{j=S+1}^{s} b_j - \sum_{j=R+1}^{r} d_j, \qquad A_0 = \sum_{j=1}^{s} b_j - \sum_{j=1}^{r} d_j, \tag{4.23}$$

$$A_1 = A_1^* + \frac{D_1 - D_1^*}{2}, \qquad A_\infty^* = 0. \tag{4.24}$$

The functions $\varphi(p)$ and $\varphi_\lambda^\star(p)$ in (4.11) and (4.17) are identically equal to 0, and $\psi_\infty(p) = A_1^*$. We have

$$\psi_0(p) \; = \; A_1^* + (1-p)\left(\sum_{j=1}^{S} b_j - \sum_{j=1}^{R} d_j\right) + \frac{p}{2}\left(D_1 - D_1^*\right), \tag{4.25}$$

$$\psi_\lambda^\star(p) \; = \; A_1^* + \frac{D_1}{2} - (1-p)\left(\sum_{\alpha_j \lambda = -1} b_j - \sum_{\gamma_j \lambda = -1} d_j\right) + \frac{D_\lambda}{2\,\lambda}. \tag{4.26}$$

where D_λ is the difference between the number of α_j's equal to $-1/\lambda$ and the number of γ_j's equal to $-1/\lambda$. This example is continued below as Example 5.2.

5 Further notation

The notation of the previous Section adds up the the parameters α_j, β_j, b_j. Here we introduce some "multiplicative" notation. Recall the convention $0^0 = 1$.

We introduce the following constants:

$$z_0 = \theta \prod \beta_j^{\beta_j}, \qquad z_1 = \theta \prod_{\alpha_j \neq 0} \alpha_j^{\beta_j} \prod_{\alpha_j = 0} \beta_j^{\beta_j}, \qquad z_\infty = \theta \prod_{\alpha_j \neq 0} \alpha_j^{\beta_j}, \tag{5.1}$$

$$\zeta_0 = \xi \prod \alpha_j^{\alpha_j}, \qquad \zeta_1 = \xi \prod_{\beta_j \neq 0} \beta_j^{\alpha_j} \prod_{\beta_j = 0} \alpha_j^{\alpha_j}. \tag{5.2}$$

Besides, we define the function

$$g(t) = |\theta|\, |\xi|^t \prod |\beta_j + \alpha_j t|^{\beta_j + \alpha_j t}. \tag{5.3}$$

We have the following properties of $g(t)$.

Lemma 5.1 *(i) The function $g(t)$ is continuous on the whole real axis. It can be expressed as follows:*

$$g(t) = |z_1|\,|\zeta_0|^t \prod_{\alpha_j \neq 0} \left| t + \frac{\beta_j}{\alpha_j} \right|^{\beta_j + \alpha_j t}. \tag{5.4}$$

(ii) $g(t)$ is continuously differentiable on $\mathbb{R} \setminus (\{0\} \cup \Omega)$, and

$$\begin{aligned} \exp \frac{g'(t)}{g(t)} &= |\xi|\ \exp(D_0^*) \prod |\beta_j + \alpha_j t|^{\alpha_j} &(5.5)\\ &= |\zeta_0|\ \exp(D_0^*) \prod_{\alpha_j \neq 0} \left| t + \frac{\beta_j}{\alpha_j} \right|^{\alpha_j}. &(5.6) \end{aligned}$$

(iii) A point $\lambda \in \{0\} \cup \Omega$ is a genuine point of discontinuity of the derivative $g'(t)$ if and only if $\sum_{\beta_j + \alpha_j \lambda = 0} \alpha_j \neq 0$. If this is the case, then the tangent line to $g(t)$ approaches the vertical line as $t \to \lambda$.

(iv) $g(0) = |z_0|$.

(v) $g(t) \sim |z_1|\ \exp(D_1)\ |\zeta_0|^t\ t^{D_0^* t + D_1}$ as $t \to \infty$.

Proof. Consider the function

$$f(x) = \begin{cases} |x|^x, & \text{if } x \neq 0, \\ 1, & \text{if } x = 0. \end{cases} \tag{5.7}$$

We can write $f(x) = \exp(x \log |x|)$ for nonzero x. It is a standard analysis exercise that $f(x)$ is a continuous function. Since $f'(x) = (1 + \log |x|)\, f(x)$, the function $f(x)$ is continuously differentiable on $\mathbb{R} \setminus \{0\}$. Expressions (5.4)–(5.6) routinely follow.

For part *(iii)*, we compute that as $t \to \lambda$,

$$\exp \frac{g'(t)}{g(t)} \sim |\xi| \prod_{\beta_j + \alpha_j \lambda \neq 0} |\beta_j + \alpha_j \lambda|^{\alpha_j} \prod_{\beta_j + \alpha_j \lambda = 0} |\alpha_j|^{\alpha_j}\ \exp(D_0^*)\, |t - \lambda|^{\sum_{\beta_j + \alpha_j \lambda = 0} \alpha_j}. \tag{5.8}$$

Hence, as $t \to \lambda$,

$$g'(t) \sim \left(C_0 + \log |t - \lambda| \sum_{\beta_j + \alpha_j\, \lambda = 0} \alpha_j \right) g(\lambda) \tag{5.9}$$

for a constant C_0. Part *(iii)* is evident.

Part *(iv)* is obvious. To show the asymptotic expression of part *(v)*, we use (5.4) to derive

$$g(t) = |z_1|\,|\zeta_0|^t\,t^{D_0^*t+D_1}\prod_{\alpha_j\neq 0}\left|1+\frac{\beta_j}{\alpha_j t}\right|^{\alpha_j t}. \tag{5.10}$$

Whether $\lambda > 0$ or $\lambda < 0$, we have $\left(1+\frac{\ell}{\lambda t}\right)^{\lambda t} \to \exp(\ell)$ as $t \to \infty$. QED.

For completeness, one can compute that

$$\exp\frac{g'(t)}{g(t)} \;\sim\; |\zeta_1|\,\exp(D_0^*)\,t^{D_0^*-D_1^*} \qquad \text{as } t \to +0. \tag{5.11}$$

$$\exp\frac{g'(t)}{g(t)} \;\sim\; |\zeta_0|\,\exp(D_0^*)\,t^{D_0^*} \qquad \text{as } t \to \infty. \tag{5.12}$$

The first expression is a special case of (5.8). The function $g(t)$ is examined more closely in Section 9.

At the last, we introduce the family of functions

$$\Phi_\lambda(x) = \sum_{\alpha_j\lambda+\beta_j\neq 0}\frac{\alpha_j^2\,x}{\alpha_j x+\alpha_j\lambda+\beta_j}. \tag{5.13}$$

In particular,

$$\Phi_0(x) = \sum_{\beta_j\neq 0}\frac{\alpha_j^2\,x}{\alpha_j x+\beta_j}. \tag{5.14}$$

We also introduce

$$\Phi_\infty(x) = \sum_{\alpha_j\neq 0}\frac{\beta_j^2\,x}{\beta_j x+\alpha_j}. \tag{5.15}$$

This is almost all notation we will need to describe the constants we have to check to determine uniformly dominated convergence of $\mathcal{U}(n)$.

Example 5.2 Continuing Example 4.5, we have:

$$z_0 = Z, \qquad z_1 = z_\infty = Z\,\frac{\prod_{j=1}^S \alpha_j}{\prod_{j=1}^R \gamma_j}, \qquad \zeta_0 = 1, \qquad \zeta_1 = \frac{\prod_{j=1}^R \gamma_j^{\gamma_j}}{\prod_{j=1}^S \alpha_j^{\alpha_j}}, \tag{5.16}$$

$$g(t) = |Z|\prod_{j=1}^{S}\frac{|\alpha_j t+1|^{\alpha_j t+1}}{|\alpha_j t|^{\alpha_j t}}\prod_{j=1}^{R}\frac{|\gamma_j t|^{\gamma_j t}}{|\gamma_j t+1|^{\gamma_j t+1}}. \tag{5.17}$$

We also have

$$\begin{aligned}
\Phi_\lambda(x) &= \sum_{\alpha_j\lambda\neq-1} \frac{\alpha_j^2\,x}{\alpha_j x+\alpha_j\lambda+1} - \sum_{\gamma_j\lambda\neq-1} \frac{\gamma_j^2\,x}{\gamma_j x+\gamma_j\lambda+1} - \frac{D_1^*\,x}{x+\lambda},\\
\Phi_0(x) &= \sum_{j=1}^{S} \frac{\alpha_j^2\,x}{\alpha_j x+1} - \sum_{j=1}^{R} \frac{\gamma_j^2\,x}{\gamma_j x+1},\\
\Phi_\infty(x) &= \sum_{j=1}^{S} \frac{x}{x+\alpha_j} - \sum_{j=1}^{R} \frac{x}{x+\gamma_j}.
\end{aligned} \tag{5.18}$$

Somewhat more generally, if we multiply the hypergeometric series in (4.21) by the gamma factor

$$\frac{\Gamma(n+a_1)\,\cdots\,\Gamma(n+a_K)}{\Gamma(n+c_1)\,\cdots\,\Gamma(n+c_L)}, \tag{5.19}$$

then the following values and functions in Examples 4.5 and 5.2 change: A^*_∞, A_1, A_1^* and $\psi^*_\lambda(p)$ are increased by $\sum a_i - \sum c_i$; the functions $\psi_0(p)$ and $\psi_\infty(p)$ are increased by $p\left(\sum a_i - \sum c_i\right)$; we get $D_0^* = K - L$; the function $\Psi_\lambda(x)$ is increased by $(K-L)x/(x+\lambda)$; and the function $g(t)$ gets multiplied by $t^{(K-L)\,t}$. In particular, if $K = L$ and $\sum a_i = \sum c_i$, then none of the introduced values and functions changes.

6 The main result

Our main result is the following.

Theorem 6.1 *The series $\mathcal{U}(n) = \sum_k u(n,k)$ defined by (4.1) is uniformly bounded by an absolutely convergent series only if the following restrictions are satisfied:*

(i) $D_0 \le 0$ *and* $D_0^* \le 0$.

(ii) If $D_0 = 0$ *then one of the following two conditions must hold:*

- $|z_0| < 1$.
- $|z_0| = 1$, $\operatorname{Re} A_0 < 0$ *and* $D_1^* \le 0$.

(iii) If $D_0^* = 0$ *then one of the following three conditions must hold:*

- $|\zeta_0| < 1$.

- $|\zeta_0| = 1$, $\operatorname{Re} A^*_\infty < 0$ *and* $D_1 \le 0$.
- $\zeta_0 = 1$, $A^*_\infty = 0$ *and* $D_1 \le 0$.

These conditions are sufficient for uniformly dominated convergence if $D_0 < 0$ *or* $D^*_0 < 0$. *Otherwise, that is when*

$$D_0 = 0 \qquad \text{and} \qquad D^*_0 = 0, \tag{6.1}$$

the series $\mathcal{U}(n)$ *are bounded by an absolutely convergent series if and only if:*

(iv) $g(t) \le 1$ *for all* $t > 0$.

(v) For those $t > 0$ *which satisfy* $g(t) = 1$, *we have* $\operatorname{Re} \psi^\star_t(0) < 0$,

$$\sum_{\alpha_j t + \beta_j = 0} \alpha_j = 0, \tag{6.2}$$

and one of the following two conditions holds:

- $\Phi_t(x) \equiv 0$; *and* $\operatorname{Re} \psi^\star_t(1) \le 0$.
- $\Phi_t(x) = v_m x^m + O(x^{m+1})$ *around* $x = 0$, *where* m *is a positive odd integer,* $v_m < 0$; *and* $\operatorname{Re} \psi^\star_t\big(\frac{m}{m+1}\big) < 0$.

(vi) If $|z_0| = 1$ *and* $D^*_1 = 0$, *then one of the following conditions holds:*

- $|\zeta_1| < 1$.
- $|\zeta_1| = 1$; $\Phi_0(x) \equiv 0$; *and* $\operatorname{Re} A_1 \le 0$.
- $|\zeta_1| = 1$; $\Phi_0(x) = v_m x^m + O(x^{m+1})$ *around* $x = 0$ *for some positive integer* m *and negative real* v_m; *and* $\operatorname{Re} \psi_0\big(\frac{m}{m+1}\big) < 0$.

(vii) If $|\zeta_0| = 1$ *and* $D_1 = 0$, *then one of the following conditions holds:*

- $|z_1| < 1$.
- $|z_1| = 1$; $\Phi_\infty(x) \equiv 0$; *and* $\operatorname{Re} A^*_1 < 0$.
- $|z_1| = 1$; $\Phi_\infty(x) \equiv 0$; $\operatorname{Re} A^*_1 = 0$; *and either* $\operatorname{Re} A^*_\infty < 0$ *or*

$$\deg_{\{n,k\}} P(n,k) > \deg_n P(n,k) + \deg_k Q(k). \tag{6.3}$$

- $|z_1| = 1$; $\Phi_\infty(x) = v_m x^m + O(x^{m+1})$ *around* $x = 0$ *for some positive integer* m *and negative real* v_m; $\operatorname{Re} \psi_\infty\big(\frac{m+1}{m}\big) < 0$; *and if* $A^*_\infty = 0$ *then* $\operatorname{Re} A^*_0 < 0$.

If these conditions are satisfied, then the limit series $\lim_{n\to\infty}\mathcal{U}(n)$ *is equal to:*

- *If* $D_0^* < 0$, $|\zeta_0| < 1$ *or* $\operatorname{Re} A_\infty^* < 0$, *then* 0.
- *If* $D_0^* = 0$, $\zeta_0 = 1$, $A_\infty^* = 0$ *and* $D_1 < 0$, *then* $H_0\, Q(0)$.
- *If* $D_0^* = 0$, $\zeta_0 = 1$, $A_\infty^* = 0$ *and* $D_1 = 0$, *then*

$$\lim_{n\to\infty} \mathcal{U}(n) = H_0 \sum_{k=0}^{\infty} Q(k)\, \frac{z_\infty^k}{k!} \prod_{\alpha_j=0} (b_j)_{\beta_j\, k}, \tag{6.4}$$

where H_0 *is the following constant:*

$$H_0 = (2\pi)^{\sum_{\alpha_j\neq 0} \frac{1-\alpha_j}{2}} \prod_{\alpha_j\neq 0} \frac{|\alpha_j|^{b_j-\frac{1}{2}}}{\Gamma(b_j)} \Bigg/ \prod_{\alpha_j<0} 2\sin \pi b_j\ . \tag{6.5}$$

We prove this Theorem in the following Section.

Here we make a few comments. We reformulate some conditions, or indicate some possible or typically effective simplifications. We keep some redundancy in notation or formulation to make the proof more smooth, or to make nontypical complications better understandable.

(I) Uniformly dominated convergence of $\mathcal{U}(n)$ does not change if it is multiplied by the gamma term in (5.19) with $K = L$ and $\sum a_i = \sum c_i$, because that does not change any of the introduced values and functions.

(II) Condition (6.3) means that among the monomials of $P(n,k)$ of the highest degree in n, k there are no monomials of the highest degree in n. Recall that $Q(k)$ is defined in (4.10).

(III) Equality (6.2) is trivially satisfied if $t \notin \Omega$. Recall that the set Ω is defined in (4.15).

(IV) Let B_1 denote the constant in (4.20). If $t \notin \Omega$, then the function $\psi_t^\star(p)$ in condition *(v)* is rather simple:

$$\psi_t^\star(p) = B_1 - \varphi(1) + \varphi_t^\star(p). \tag{6.6}$$

From part *(i)* of Lemma 4.3 it follows that $\psi_t^\star(p) \le B_1$ for $p \in [0,1]$, and $\psi_t^\star(1) = B_1$. For generic p we have $\psi_t^\star(p) = B_1$ for $p \in [0,1]$.

If $t \notin \Omega$, $g(t) = 1$ and $\Phi_t(x) \equiv 0$, the condition *(v)* can be replaced by the following restriction: either $\operatorname{Re} B_1 < 0$, or $\operatorname{Re} B_1 = 0$ and $\deg_k P(tk,k) < \deg_{\{n,k\}} P(n,k)$. If we can apply this simpler restriction to at least one $t \notin \Omega$, then the points $t \notin \Omega$ with $g(t) = 1$, $\Phi_t(x) \not\equiv 0$ can only strengthen $\operatorname{Re} B_1 = 0$ to $\operatorname{Re} B_1 < 0$ and add conditions on $\Phi_t(x)$.

(V) Condition (6.2) is equivalent to $\sum_{\alpha_j t+\beta_j=0}\beta_j = 0$. For the purposes of Theorem 6.1, we can replace the third summation in definition (4.19) of $\psi^\star_t(p)$ by the same conditional summation of $\widetilde{a}_j$'s or $b_j-\frac{1}{2}$, because the function $\psi^\star_t(p)$ is relevant only if (6.2) holds.

(VI) All conditions of Theorem 6.1 can be checked algorithmically, if all parameters in (1.1) are given numerically. The only less straightforward part is checking the condition $g(t)\le 1$ for $t>0$, and identifying the points with $g(t)=1$. We consider this issue in Section 9.

(VII) Suppose that the polynomial $P(n,k)$ has a linear factor $\widetilde{\alpha}n+\widetilde{\beta}k+\ell$ with $\widetilde{\alpha},\widetilde{\beta}\in\mathbb{Z}$. The linear factor can be expressed as $\ell\,(\ell+1)_{\widetilde{\alpha}n+\widetilde{\beta}k}\big/(\ell)_{\widetilde{\alpha}n+\widetilde{\beta}k}$. Notice that all conditions, in particular *(v)*, are stable if we rewrite expression (4.1) of $u(n,k)$ by replacing in $P(n,k)$ the linear factor by the constant ℓ, and appending the two Pochhammer terms to the product of Pochhammer symbols.

(VIII) The polynomial $Q(k)$ occurs only in (6.3) and in the expressions for $\lim_{n\to\infty}\mathcal{U}(n)$. The constant z_∞ occurs only in (6.4). The constant A_0^* occurs in the last case of condition *(vii)*. The set Ω does not explicitly appear in the formulated Theorem.

(IX) Notice that $H_0=\prod_{\alpha_j<0}\Gamma(1-b_j)\big/\prod_{\alpha_j>0}\Gamma(b_j)$ if all nonzero α_j's are equal to 1 or -1.

When discussing the function $g(t)$ in Section 9, we add a few more observations *(X)–(XIV)* to this list.

7 Examples

Example 7.1 Consider the hypergeometric series $S_1(n)={}_2\mathrm{F}_1\left(\begin{matrix}a+\alpha\,n,\,b\\ c+\gamma\,n\end{matrix}\,\middle|\,1\right)$, with α,γ nonzero integers. Following Examples 4.5 and 5.2, we have:

$$D_0=D_1=D_0^*=0,\qquad D_1^*=\alpha-\gamma,\qquad z_0=\zeta_0=1,\qquad z_1=\frac{\alpha}{\gamma},\tag{7.1}$$

$$A_0=a+b-c,\qquad A_\infty^*=0.\tag{7.2}$$

Of the conditions *(i)–(iii)*, we have *(i)* and the third option of *(iii)* satisfied. The second option of *(ii)* requires $\operatorname{Re}A_0<0$ and $D_1^*\le 0$ for uniformly dominant convergence of $S_1(n)$. We notice right away that condition *(vii)* requires $|z_1|\le 1$. This gives the following inequalities:

$$\operatorname{Re}(c-a-b)<0,\qquad \alpha\le\gamma,\qquad |\alpha|\le|\gamma|.\tag{7.3}$$

The last two inequalities mean that either $|\alpha| \le \gamma$, or $\alpha = \gamma < 0$. We consider the cases $|\alpha| < \gamma$, $\alpha = -\gamma$, $\alpha = \gamma > 0$ and $\alpha = \gamma < 0$ separately. For conditions *(iv)* and *(v)*, we have:

$$g(t) = \frac{|1+\alpha\, t|^{1+\alpha\, t}\, |\gamma\, t|^{\gamma\, t}}{|\alpha\, t|^{\alpha\, t}\, |1+\gamma\, t|^{1+\gamma\, t}}. \tag{7.4}$$

If $|\alpha| < \gamma$, then it is straightforward to check that $g(t)$ monotonically decreases from 1 to $|\alpha/\gamma|$ as t varies over $(0,\infty)$; see also part *(iii)* of Lemma 9.2 below. Then Theorem 6.1 gives no additional conditions, since $D_1^* < 0$ and $|z_1| < 1$. The series $S_1(n)$ converges uniformly, and the limit series has the value $(1-\alpha/\gamma)^{-b}$.

If $\alpha = -\gamma$ (and $\gamma > 0$), then $g(t) < 1$ for $t \in (0,\infty)$ as well; see part *(iv)* of Lemma 9.2. It remains to check condition *(vii)*; only the last option can be satisfied, since $\Psi_\infty(x) \not\equiv 0$. We compute $\psi_\infty(p) = A_0^* = b$, and

$$\Psi_\infty(x) = \frac{x}{x-\gamma} - \frac{x}{x+\gamma} = -\frac{2}{\gamma}\, x + O(x^3). \tag{7.5}$$

The restriction on $\Psi_\infty(x)$ is satisfied. But we have the additional condition $\operatorname{Re} b < 0$. The limit series has the value 2^{-b}.

If $\alpha = \gamma > 0$, then $g(t) = 1$. Then $\xi_1 = 1$, $A_1 = A_1^* = b$ and

$$\Psi_\lambda(x) \equiv 0 \qquad \text{for } \lambda = 0,\ \lambda = \infty \text{ or } \lambda \in (0,\infty), \tag{7.6}$$

$$\psi_\lambda^\star(p) = b \qquad \text{for } \lambda \in (0,\infty). \tag{7.7}$$

Besides, $P(n,k) = Q(k) = 1$. The first option of *(v)* and the second options of *(vi)*, *(vii)* are relevant. We get the additional condition $\operatorname{Re} b < 0$ here as well. The limit series has the value 0.

If $\alpha = \gamma < 0$, a crucial difference from the previous case is that the set Ω is nonempty. In particular, for $t = -1/\gamma$ we have $\psi_t^\star(p) = b + (1-p)(c-a)$. Condition *(v)* applied to this t immediately gives $\operatorname{Re} b < \operatorname{Re}(a-c)$. This is an additional condition to $\operatorname{Re} b < 0$ and $\operatorname{Re}(c-a-b) > 0$.

If we assume $\alpha = 0$ and $\gamma > 0$ for the same series $S_1(n)$, then the series converges uniformly if $\operatorname{Re}(c-a-b) > 0$, because

$$D_0 = D_0^* = 0, \quad D_1 = -1, \quad D_1^* = -\gamma, \qquad z_0 = \zeta_0 = 1, \tag{7.8}$$

$$A_0 = a+b-c, \qquad A_\infty^* = 0, \tag{7.9}$$

and $g(t) < 1$ for all $t > 0$. See also [Ko98, Section 2]. On the other hand, if $\alpha = 0$ and $\gamma < 0$, then $D_1^* > 0$ in condition *(ii)*. Then the limit series do not converge.

In conclusion, the hypergeometric series ${}_2\mathrm{F}_1\left(\begin{matrix} a+\alpha\,n, b \\ c+\gamma\,n \end{matrix} \,\middle|\, 1\right)$ converges uniformly in the following situations:

- $|\alpha| < \gamma$ and $\mathrm{Re}\,(c-a-b) > 0$.
- $|\alpha| = \gamma$, and $\mathrm{Re}\,(c-a-b) > 0$ and $\mathrm{Re}\,b < 0$.
- $\alpha = \gamma < 0$, and $\mathrm{Re}\,b < -\left|\mathrm{Re}\,(c-a)\right|$.

Notice that the series ${}_2\mathrm{F}_1\left(\begin{matrix} a+\alpha\,n, b+\beta\,n \\ c+\gamma\,n \end{matrix} \,\middle|\, 1\right)$ with $\alpha\beta \neq 0$ cannot converge uniformly, because the termwise limit does not exist. In the setting of Theorem 6.1, we would have $D_1 > 0$, so condition *(iii)* would not be satisfied.

Example 7.2 Consider the hypergeometric series $S_2(n) = {}_2\mathrm{F}_1\left(\begin{matrix} a+\alpha\,n, b \\ c+\gamma\,n \end{matrix} \,\middle|\, -1\right)$. Compared with the previous example, only the values z_0, z_1 (and z_∞) change — they get multiplied by -1. That does not change any of the conditions of Theorem 6.1. Hence we have the same uniform convergence cases as in the previous example.

In particular, the well poised series ${}_2\mathrm{F}_1\left(\begin{matrix} a+2n, b \\ 1+a-b+2n \end{matrix} \,\middle|\, -1\right)$ converges uniformly if $\mathrm{Re}\,b < 0$, as used in [Gau99]. The limit series has the value 2^{-b}. But the series ${}_2\mathrm{F}_1\left(\begin{matrix} a-2n, b \\ 1+a-b-2n \end{matrix} \,\middle|\, -1\right)$ fails the test of Theorem 6.1, because of a contradictory condition $\mathrm{Re}\,b < \mathrm{Re}\,(b-1)$.

Similarly, the well poised series ${}_2\mathrm{F}_1\left(\begin{matrix} a, b-n \\ 1+a-b+n \end{matrix} \,\middle|\, -1\right)$ converges uniformly if $\mathrm{Re}\,b < \frac{1}{2}$ and $\mathrm{Re}\,a < 0$. The limit series has the value 0. Recall that well poised ${}_2\mathrm{F}_1(-1)$ series can be evaluated using Kummer's formula [AAR99, Cor. 3.1.2].

Example 7.3 Consider the hypergeometric series $S_3(n) = {}_2\mathrm{F}_1\left(\begin{matrix} a+\alpha\,n, b, c \\ d+\gamma\,n, f \end{matrix} \,\middle|\, 1\right)$. Compared with Example 7.1, we have $A_0 = a+b+c-d-f$ and $\psi_\infty(p) = A_0^* = A_1 = A_1^* = b+c-f$. The functions $\psi_\infty(p)$ and $\psi_\lambda^\star(p)$ are different similarly. With the same reasoning as in Example 7.1, we get the following cases of uniformly dominant convergence of $S_3(n)$:

- $|\alpha| < \gamma$ and $\mathrm{Re}\,(d+f-a-b-c) > 0$.
- $|\alpha| = \gamma$, $\mathrm{Re}\,(d+f-a-b-c) > 0$ and $\mathrm{Re}\,(b+c-f) < 0$.
- $\alpha = \gamma < 0$, $\mathrm{Re}\,(b+c-f) < -\left|\mathrm{Re}\,(d-a)\right|$.

In particular, if the series $S_3(n)$ is balanced (that is, if $d+f = a+b+c+1$ and $\alpha = \gamma$), it converges uniformly in the following two situations:

- If $\gamma > 0$ and $\mathrm{Re}\,(b+c-f) < 0$; see also [Ko98, Section 3].
- If $\gamma < 0$ and $\mathrm{Re}\,(b+c-f) < -\frac{1}{2}$.

We can replace $\mathrm{Re}\,(b+c-f)$ by $\mathrm{Re}\,(d-a-1)$ in these two conditions.

8 Proof of the main theorem

Here we prove Theorem 6.1. The strategy is outlined by Lemma 2.2.

With our notation and summation/product conventions, we may split the hypergeometric summand $u(n,k)$ in the following ways. Firstly, we can switch to variables in (4.2)–(4.3) as follows:

$$u(n,k) = \prod_{\beta_j=0} \left(\widetilde{a}_j + \tfrac{1-\alpha_j}{2}\right)_{\alpha_j\, n} \xi^n\, P(n,k) \prod \left(\widehat{a}_j + \tfrac{1-\beta_j}{2}\right)_{\beta_j\, k+\alpha_j\, n} \frac{\theta^k}{k!}. \tag{8.1}$$

In another way, we can split the Pochhammer symbols in other way and obtain the following expression for $u(n,k)$:

$$\prod \left(\widetilde{a}_j + \tfrac{1-\alpha_j}{2}\right)_{\alpha_j\, n} \xi^n\, P(n,k) \prod_{\alpha_j\neq 0} \left(\widehat{a}_j + \tfrac{1-\beta_j}{2} + \alpha_j n\right)_{\beta_j\, k} \prod_{\alpha_j=0} \left(\widehat{a}_j + \tfrac{1-\beta_j}{2}\right)_{\beta_j\, k} \frac{\theta^k}{k!}. \tag{8.2}$$

Note that here the first two factors do not depend on k, and the last two terms do not depend on n. We will use these expressions in different cases of Lemma 2.2.

Condition *(a)* of Lemma 2.2 is satisfied under the following necessary and sufficient restrictions:

(a1) $D_0 \le 0$.

(a2) If $D_0 = 0$, then $|z_0| \le 1$.

(a3) If $D_0 = 0$, $|z_0| = 1$, then $D_1^* \le 0$ and $\operatorname{Re} A_0 < 0$.

because for fixed general n we have

$$\begin{aligned} u(n,k) \;&\sim\; C(n)\, k^{\deg_k P(n,k)+\sum(\widehat{a}_j+\alpha_j n)}\, \frac{\theta^k}{k!}\, \Gamma(k)^{\sum \beta_j} \prod \beta_j^{\beta_j k} && (8.3)\\ &\sim\; C(n)\, k^{D_1^*\, n+A_0-1}\, z_0^k\, \Gamma(k)^{D_0}. && (8.4) \end{aligned}$$

Recall that $k! = k\,\Gamma(k)$. These conditions are general convergence conditions for hypergeometric series; see [AAR99, Theorems 2.1.1–2].

For condition *(b)* of Lemma 2.2, we fix general k and use (8.2), Corollary 2.5:

$$\begin{aligned} u(n,k) \;\sim\;& n^{\deg_n P(n,k)+\sum(\widetilde{a}_j+\beta_j k)}\, \xi^n\, \Gamma(n)^{\sum \alpha_j} \prod \alpha_j^{\alpha_j\, n} \\ & \times H_0\, Q(k)\, \frac{\theta^k}{k!} \prod_{\alpha_j\neq 0} \alpha_j^{\beta_j k} \prod_{\alpha_j=0} \left(\widehat{a}_j + \tfrac{1-\beta_j}{2}\right)_{\beta_j\, k}. \end{aligned} \tag{8.5}$$

Here H_0 and $Q(k)$ are the same as in (6.5), (4.10). The first line of the right-hand side can be rewritten as $n^{D_1 k + A^*_\infty}\, \zeta_0^n\, \Gamma(n)^{D^*_0}$. The second line is independent of n. For the existence of the termwise limit we first check whether $u(n,k)$ is bounded as $n \to \infty$, and whether the limit $\lim_{n\to\infty} u(n,0)$ exists:

(b1) $D^*_0 \leq 0$.

(b2) If $D^*_0 = 0$, then $|\zeta_0| \leq 1$.

(b3) If $D^*_0 = 0$, $|\zeta_0| = 1$, then $D_1 \leq 0$ and $\operatorname{Re} A^*_\infty \leq 0$.

(b4) If $D^*_0 = 0$, $|\zeta_0| = 1$, $\operatorname{Re} A^*_\infty = 0$, then $\zeta_0 = 1$ and $A^*_\infty = 0$.

Under these conditions the termwise limit $\lim_{n\to\infty} \mathcal{U}(n)$ is the zero series if $D^*_0 < 0$, $|\zeta_0| < 1$ or $\operatorname{Re} A^*_\infty < 0$. Otherwise condition *(b4)* applies. Then the termwise limit is $H_0\, Q(0)$ if $D_1 < 0$, and it is equal to (6.4) if $D_1 = 0$. In these cases, asymptotics (8.5) can be rewritten, up to a constant factor, as $k^{A^*_0 - 1}\, z_1^k\, \Gamma(k)^{D_0 - D_1}$. Additional conditions for the convergence of the limit series are the following:

(b5) If $D^*_0 = 0$, $\zeta_0 = 1$, $D_1 = 0$, $A^*_\infty = 0$, then $D_0 \leq 0$.

(b6) If $D^*_0 = 0$, $\zeta_0 = 1$, $D_1 = 0$, $A^*_\infty = 0$, $D_0 = 0$, then $|z_1| \leq 1$.

(b7) If $D^*_0 = 0$, $\zeta_0 = 1$, $D_1 = 0$, $A^*_\infty = 0$, $D_0 = 0$, $|z_1| = 1$, then $\operatorname{Re} A^*_0 < 0$.

Now we check condition *(c)* of Lemma 2.2. We assume that $N = N(k)$ is an integer-valued function such that $N(k) \sim C_0\, k^p$ as $k \to \infty$, with $p > 1$ and $C_0 > 0$ real constants. Using formula (8.2), Corollaries 2.4 and 3.4 we get the following asymptotic expression as $k \to \infty$:

$$\begin{aligned} u(N,k) \;\; \sim \;\; & C_1\, N^{\sum \widetilde{a}_j} \prod \alpha_j^{\alpha_j N}\, \Gamma(N)^{\sum \alpha_j}\, \xi^N\, P(N,k) \prod_{\alpha_j \neq 0} \alpha_j^{\beta_j\, k}\, N^{\sum_{\alpha_j \neq 0} \beta_j k} \\ & \times \exp\left(k\, \widetilde{\Phi}_\infty\!\left(\frac{k}{N}\right)\right) k^{\sum_{\alpha_j = 0} \widehat{a}_j} \prod_{\alpha_j = 0} \beta_j^{\beta_j\, k}\, \Gamma(k)^{\sum_{\alpha_j = 0} \beta_j}\, \frac{\theta^k}{k!}, \end{aligned} \tag{8.6}$$

for some $C_1 \in \mathbb{R}$, and

$$\widetilde{\Phi}_\infty(x) = \sum_{\alpha_j \neq 0} \beta_j\, \Theta\!\left(\frac{\beta_j\, x}{\alpha_j}\right). \tag{8.7}$$

We rearrange as

$$
\begin{aligned}
u(N,k) \;\; &\sim \;\; C_1\,\Gamma(N)^{D_0^*}\;\zeta_0^N\,\Gamma(k)^{D_0}\;\left(\frac{N^k}{\Gamma(k)}\right)^{D_1}\;z_1^k\;\exp\left(k\,\widetilde{\Phi}_\infty\Big(\frac{k}{N}\Big)\right)\\
&\quad \times P(N,k)\;k^{(\sum \widetilde{a}_j)\,p+\sum_{\alpha_j=0}\widehat{a}_j-1}. \qquad (8.8)
\end{aligned}
$$

We compute that, as $k \to \infty$,

$$
\begin{aligned}
\frac{\log|u(N,k)|}{k} \;\; &= \;\; D_0^*\,\frac{N\log N - N}{k} + \frac{N}{k}\,\log|\zeta_0| + D_0\,(\log k - 1)\\
&\quad + D_1\left(\log\frac{N}{k}+1\right) + \log|z_1| + o(1). \qquad (8.9)
\end{aligned}
$$

Note that $\log(N/k) \sim (p-1)\,\log k + O(1)$.

To investigate absolute convergence of $\sum_{k=0}^{\infty} u(N,k)$, we first look at formula (8.9) and use Lemma 3.6 with $\varrho = 1$. The series must converge absolutely for all relevant $N = N(k)$. The most subtle case is when the expression in (8.9) is $o(1)$. Eventually we get the following list of conditions:

- *(c1)* $D_0^* \le 0$.
- *(c2)* If $D_0^* = 0$, then $|\zeta_0| \le 1$.
- *(c3)* If $D_0^* = 0$, $|\zeta_0| = 1$, then $D_0 \le 0$ and $D_1 \le 0$.
- *(c4)* If $D_0^* = 0$, $|\zeta_0| = 1$, $D_0 = 0$, $D_1 = 0$, then $|z_1| \le 1$.
- *(c5)* If $D_0^* = 0$, $|\zeta_0| = 1$, $D_0 = 0$, $D_1 = 0$, $|z_1| = 1$, then $\mathrm{Re}\,A_\infty^* \le 0$ and one of the following conditions holds:
  - *(c5A)* $\widetilde{\Phi}_\infty(x) \equiv 0$, and $\mathrm{Re}\,A_1^* < 0$.
  - *(c5B)* $\widetilde{\Phi}_\infty(x) \equiv 0$, $\mathrm{Re}\,A_1^* = 0$, and either $\deg_{\{n,k\}} P(n,k) > \deg_n P(n,k) + \deg_k Q(k)$ or $\mathrm{Re}\,A_\infty^* < 0$.
  - *(c5C)* $\widetilde{\Phi}_\infty(x) = v_m x^m + O(x^{m+1})$ around $x = 0$ for some positive integer m and negative real v_m, and $\mathrm{Re}\;\psi_\infty\big(\frac{m+1}{m}\big) < 0$.

Here we comment the case when the expression in (8.9) is $o(1)$ as $k \to \infty$. Formula (8.8) becomes then, for general $N(k)$ by the first two parts of Lemma 4.1,

$$
u(N,k) \sim \widetilde{C}_1\;\exp\left(k\,\widetilde{\Phi}_\infty\Big(\frac{k}{N}\Big)\right)\;k^{\,\psi_\infty(p)-1}, \qquad (8.10)
$$

for some $\widetilde{C}_1 \in \mathbb{R}$. To have convergence for large p, we must have $\operatorname{Re} A^*_\infty \le 0$. If $\widetilde{\Phi}_\infty(x) \equiv 0$ we must have $\operatorname{Re}\psi_\infty(p) < 0$ for all $p \in (1,\infty)$. By part *(ii)* of Lemma 4.2, the real part of $\psi_\infty(p)$ approaches its supremum with $p \mapsto 1$. The condition $\operatorname{Re}\psi_\infty(p) < 0$ is ensured in Case *(c5A)*. The Case *(c5B)* occurs when the supremum is not achieved inside the interval $(1,\infty)$. If $\widetilde{\Phi}_\infty(x) \not\equiv 0$, then the exponential factor in (8.10) is asymptotic to

$$\exp\left(\frac{v_m}{C_0^m}\, k^{1-(p-1)\,m}\right). \tag{8.11}$$

For $p \ge \frac{m+1}{m}$ then the exponential factor is asymptotically a constant. Then we must have $\operatorname{Re}\psi_\infty(p) < 0$ for all $p \in \left[\frac{m+1}{m},\infty\right)$; by part *(iii)* of Lemma 4.2 we have to check the value $\operatorname{Re}\psi_\infty\left(\frac{m+1}{m}\right)$. If $p < \frac{m+1}{m}$ then the exponential factor determines convergence; the condition on v_m follows from Lemma 3.6 with $\varrho = 1-(p-1)\,m$.

Now we check condition *(d)* of Lemma 2.2. We assume that $N(k) \sim C_0\, k^p$, where $p \in (0,1)$ and $C_0 > 0$ are real constants. Using formula (8.1), Corollary 2.4 and Lemma 3.3, we get the following asymptotic expression as $k \to \infty$:

$$\begin{aligned} u(N,k) \;\; &\sim \;\; C_1\, N^{\sum_{\beta_j=0}\widetilde{a}_j} \prod_{\beta_j=0} \alpha_j^{\alpha_j N}\, \Gamma(N)^{\sum_{\beta_j=0}\alpha_j}\, \xi^N \prod_{\beta_j\neq 0} \beta_j^{\alpha_j N} \prod \beta_j^{\beta_j\, k}\, k^{\sum_{\beta_j\neq 0}\alpha_j N} \\ &\qquad \times \exp\left(N\,\widetilde{\Phi}_0\!\left(\frac{N}{k}\right)\right) P(N,k)\, k^{\sum \widehat{a}_j}\, \Gamma(k)^{\sum \beta_j}\, \frac{\theta^k}{k!}, \end{aligned} \tag{8.12}$$

where $C_1 \in \mathbb{R}$, and

$$\widetilde{\Phi}_0(x) = \sum_{\beta_j\neq 0} \alpha_j\, \Theta\!\left(\frac{\alpha_j\, x}{\beta_j}\right). \tag{8.13}$$

We rearrange as

$$\begin{aligned} u(N,k) \;&\sim\; C_0\, \Gamma(k)^{s-r-1}\, z_0^k\, \Gamma(N)^{S-R} \left(\frac{k^N}{\Gamma(N)}\right)^{\widetilde{S}-\widetilde{R}} \zeta_1^N\, \exp\!\left(N\,\widetilde{\Phi}_0\!\left(\frac{N}{k}\right)\right) \\ &\qquad \times P(n,k)\, k^{\sum \widehat{a}_j - \sum \widehat{c}_j + \left(\sum_{\beta_j=0}\widetilde{a}_j - \sum_{\delta_j=0}\widetilde{c}_j\right)p-1}, \end{aligned} \tag{8.14}$$

We compute that

$$\begin{aligned} \frac{\log|s(N,k)|}{k} \;&=\; D_0\,(\log k - 1) + \log|z_0| + D_0^*\,\frac{N}{k}\big(p\,\log k - 1\big) \\ &\qquad + D_1^*\,\frac{N}{k}\big((1-p)\log k + 1\big) + \frac{N}{k}\,\log|\zeta_1| + o\left(k^{-1+p}\right). \end{aligned} \tag{8.15}$$

The last two expressions can be conveniently compared with (8.8)–(8.9). Currently, $k \gg N$. Like in the previous case, first we consider formula (8.15) and use Lemma 3.6 with $\varrho = p$. We get a similiar set of conditions:

(d1) $D_0 \le 0$.

(d2) If $D_0 = 0$ then $|z_0| \le 1$.

(d3) If $D_0 = 0$, $|z_0| = 1$, then $D_0^* \le 0$ and $D_1^* \le 0$.

(d4) If $D_0 = 0$, $|z_0| = 1$, $D_0^* = 0$, $D_1^* = 0$, then $|\zeta_1| \le 1$.

(d5) If $D_0 = 0$, $|z_0| = 1$, $D_0^* = 0$, $D_1^* = 0$, $|\zeta_1| = 1$, then $\operatorname{Re} A_0 < 0$ and one of the following conditions holds:

  (d5A) $\widetilde{\Phi}_0(x) \equiv 0$ and $\operatorname{Re} A_1 \le 0$.

  (d5B) $\widetilde{\Phi}_0(x) = v_m x^m + O(x^{m+1})$ around $x = 0$ for some positive integer m and negative real v_m, and $\operatorname{Re} \psi_0\big(\frac{m}{m+1}\big) < 0$.

In condition *(d5)*, we may consider possibilities for $\operatorname{Re} A_0 = 0$, but this is unnecessary because of condition *(a3)*. In condition *(d5A)*, the case $\operatorname{Re} A_1 = 0$ ought to be supplemented by conditions that $\operatorname{Re} \psi_0(p) \ne 0$ for all $p < 1$; but this is obsolete, since if the linear slope of $\operatorname{Re} \psi_0(p)$ immediately to the left of $p = 1$ is zero, then the supremum is approached with $p \to 0$ by part *(iii)* of Lemma 4.2.

The case when the expression in (8.15) is $o(k^{-1+p})$ is similar to the consideration of $o(1)$ in (8.9). Formula (8.14) becomes then, for general $N(k)$,

$$u(N, k) \sim \widetilde{C}_1 \exp\left(N\, \widetilde{\Phi}_0\left(\frac{N}{k}\right)\right) k^{\psi_0(p)-1}, \tag{8.16}$$

for some $\widetilde{C}_1 \in \mathbb{R}$. If $\widetilde{\Phi}_0(x) \equiv 0$ we must have $\operatorname{Re} \psi_0(p) < 0$ for all $p \in (0, 1)$. By part *(ii)* of Lemma 4.2, we have to check the behavior of $\psi_0(p)$ near the end-points $p = 0$ and $p = 1$. If $\widetilde{\Phi}_0(x) \not\equiv 0$, then the exponential factor in (8.16) is asymptotic to

$$\exp\left(v_m C_0^{m+1}\, k^{p-(1-p)\,m} \right). \tag{8.17}$$

For $p \le \frac{m}{m+1}$ then the exponential factor is asymptotically a constant. Then we must have $\operatorname{Re} \psi_0(p) < 0$ for all $p \in \big(0, \frac{m}{m+1}\big]$; by part *(iii)* of Lemma 4.2 we have to check the values $\psi_0\big(\frac{m}{m+1}\big)$ and $\psi_0(0)$. If $p > \frac{m}{m+1}$ then the exponential factor determines convergence; the condition on v_m follows from Lemma 3.6 with $\varrho = p - (1 - p)\, m$.

It remains to check condition *(e)* of Lemma 2.2. Let us define the family of functions:

$$\widetilde{\Phi}_\lambda(x) = \sum_{\alpha_j\lambda+\beta_j\neq 0} \alpha_j\,\Theta\biggl(\frac{\alpha_j\,x}{\alpha_j\,\lambda+\beta_j}\biggr)\,. \tag{8.18}$$

We split condition *(e)* into two cases:

- ($\star$) $N(k) = tk + \omega(k)$ with real positive $t \notin \Omega$, and either $\omega(k) = O(1)$ or $\omega(k) \sim C_0 k^p$ for some real $p \in (0,1)$ and C_0.
- ($\star\star$) $N(k) = tk + \omega(k)$ with real positive $t \in \Omega$, and either $\omega(k) = O(1)$ or $\omega(k) \sim C_0 k^p$ for some real $p \in (0,1)$ and C_0.

Recall that Ω is defined in (4.15).

For case ($\star$) we use formula (4.1) and Lemma 3.3 to derive the following asymptotic expression as $k \to \infty$:

$$\begin{aligned} u(N,k) \;\; &\sim \;\; C_1\,\Gamma(k)^{\sum(\beta_j+\alpha_j t)}\,\frac{\theta^k}{k!}\,\xi^N\,P(N,k)\,k^{\sum\left(\widehat{a}_j+\frac{1}{2}\alpha_j t\right)+\sum_{\beta_j=0}\left(\widetilde{a}_j+\frac{t-1}{2}\alpha_j\right)} \\ &\quad \times k^{\sum\alpha_j\,\omega(k)}\prod(\beta_j+\alpha_j t)^{\beta_j k+\alpha_j N}\,\exp\biggl(\omega(k)\,\widetilde{\Phi}_t\biggl(\frac{\omega(k)}{k}\biggr)\biggr)\,. \end{aligned} \tag{8.19}$$

for some $C_1 \in \mathbb{C}$. We arrange as follows:

$$\begin{aligned} |u(N,k)| \;\; &\sim \;\; \widetilde{C}_1\,\Gamma(k)^{\sum\alpha_j t+\sum\beta_j}\,\frac{|P(N,k)|}{k!}\,\exp\left(\omega(k)\,\widetilde{\Phi}_t\biggl(\frac{\omega(k)}{k}\biggr)\right) \\ &\quad \times \left(|\theta||\xi|^t\prod|\beta_j+\alpha_j t|^{\beta_j+\alpha_j t}\right)^k\left(|\xi|\,k^{\sum\alpha_j}\prod|\beta_j+\alpha_j t|^{\alpha_j}\right)^{\omega(k)} \\ &\quad \times k^{\mathrm{Re}\left(\sum\widehat{a}_j+\sum_{\beta_j=0}\widetilde{a}_j\right)+\frac{t-1}{2}\sum\alpha_j+\frac{1}{2}\sum_{\beta_j\neq 0}\alpha_j}. \end{aligned} \tag{8.20}$$

for some $\widetilde{C}_1 \in \mathbb{R}$. Using (4.19), (5.3), (5.5), we rewrite:

$$\begin{aligned} |u(N,k)| \;\; &\sim \;\; \Gamma(k)^{D_0^* t+D_0}\left(\frac{k^{\omega(k)+\frac{t-1}{2}}}{\exp(1)}\right)^{D_0^*} g(t)^k\,\exp\left(\omega(k)\,\frac{g'(t)}{g(t)}\right) \\ &\quad \times \exp\left(\omega(k)\,\widetilde{\Phi}_t\biggl(\frac{\omega(k)}{k}\biggr)\right)\,k^{\mathrm{Re}\,\psi_t^\star(p)-1}. \end{aligned} \tag{8.21}$$

Here we set $p = 0$ if $\omega(k) = O(1)$. Recall that $\psi_t^\star(p)$ is a monotone nondecreasing function by part *(ii)* of Lemma 4.3.

We already have $D_0 \le 0$ and $D_0^* \le 0$ by conditions *(a1)* and *(b1)*. Case $(\star)$ gives additional conditions if $D_0 = 0$ and $D_0^* = 0$. Firstly, we must have $g(t) \le 1$ for all positive $t \in \mathbb{R} \setminus \Omega$. If this is the case, and $g(t_0) = 1$ for some positive $t_0 \in \mathbb{R} \setminus \Omega$, then $g'(t_0) = 0$. Indeed, $g(t_0) \ne 0$ would imply $g(t_1) > 1$ for some $t_1 \in \mathbb{R} \setminus \Omega$ in a neighborhood of t_0. Therefore we may ignore the exponential factor with $g'(t)$. At these points t_0 we have to consider the last two terms in (8.21). Eventually we get the following conditions for the case $(\star)$:

- *(e1)* If $D_0 = 0$, $D_0^* = 0$, then $g(t) \le 1$ for all positive $t \in \mathbb{R} \setminus \Omega$.
- *(e2)* If $D_0 = 0$, $D_0^* = 0$, and $g(t) = 1$ for some positive $t \in \mathbb{R} \setminus \Omega$, then for any $t_0 \in \mathbb{R} \setminus \Omega$ where $g(t_0) = 1$, we must have $\operatorname{Re} \psi^\star_{t_0}(0) < 0$ and one of the following two conditions satisfied:
  - *(e2A)* $\widetilde{\Phi}_{t_0}(x) \equiv 0$, and $\operatorname{Re} \psi^\star_{t_0}(1) \le 0$.
  - *(e2B)* $\widetilde{\Phi}_{t_0}(x) = v_m x^m + O(x^{m+1})$ around $x = 0$, where m is a positive **odd** integer, $v_m < 0$, and $\operatorname{Re} \psi^\star_{t_0}\left(\frac{m}{m+1}\right) < 0$.

Here we comment the situations when condition *(e2)* applies. We have $\operatorname{Re} \psi^\star_{t_0}(0) < 0$ because the power of k in (8.21) determines the convergence when $\omega(k) = O(1)$. If $\widetilde{\Phi}_t(x) \equiv 0$, we must have $\operatorname{Re} \psi^\star_t(p) < 0$ for all $p \in [0, 1)$. By part *(iii)* of Lemma 4.4, it is enough to have $\operatorname{Re} \psi^\star_{t_0}(1) \le 0$. If $\widetilde{\Phi}_t(x) \not\equiv 0$, then the exponential factor is asymptotic to $\exp\left(v_m\, C_0^{m+1}\, k^{p-(1-p)\,m}\right)$; it is relevant when $p \in \left(\frac{m}{m+1}, 1\right)$. If m is even, the exponential factor is unbounded either when $C_0 > 0$ or when $C_0 < 0$. Hence m must be odd. Then Lemma 3.6 with $\varrho = p - (1-p)\, m$ gives the restriction $v_m < 0$. The power of k factor must be restricted for $p \in \left[\frac{m}{m+1}, 1\right]$. By part *(iii)* of Lemma 4.4, it is enough to have $\operatorname{Re} \psi^\star_{t_0}\left(\frac{m}{m+1}\right) \le 0$.

Now we consider the case $(\star\star)$, with $t \in \Omega$. Formula (8.19) should be modified as follows:

- The sums and products should be supplemented by the condition $\beta_j + \alpha_j\, t \ne 0$. This is unnecessary for the sums in the power of $\Gamma(k)$, and eventually in some products (since $0^0 = 1$). Note that these conditions are already indicated in definition (8.18) of $\widetilde{\Phi}_t(x)$.
- By Lemma 3.5, we have to append

$$|\omega(k)|^{\sum_{\alpha_j t+\beta_j=0}\left(b_j-\frac{1}{2}\right)} \left(\sqrt{|\omega(k)|}\;\Gamma(|\omega(k)|)\right)^{\varepsilon \sum_{\alpha_j t+\beta_j=0} \alpha_j} \prod_{\alpha_j t+\beta_j=0} (\varepsilon\alpha_j)^{\alpha_j \omega(k)}. \tag{8.22}$$

With these modifications, asymptotic expression (8.21) can be written eventually as

$$
\begin{aligned}
|u(N,k)| \;\sim\; & \Gamma(k)^{D_0^*\,t+D_0}\Big(\sqrt{|\omega(k)|}\,\Gamma(|\omega(k)|)\Big)^{\varepsilon\sum_{\alpha_j t+\beta_j=0}\alpha_j}\; g(t)^k \\
& \times\left(|\xi|\prod_{\alpha_j t+\beta_j\neq 0}|\beta_j+\alpha_j t|^{\alpha_j}\prod_{\alpha_j t+\beta_j=0}|\alpha_j|^{\alpha_j}\right)^{\omega(k)}\exp\!\Big(\omega(k)\,\widetilde{\Phi}_t\Big(\frac{\omega(k)}{k}\Big)\Big) \\
& \times\, k^{D_0^*\big(\omega(k)+\frac{t-1}{2}\big)-\sum_{\alpha_j t+\beta_j=0}\big(\alpha_j\omega(k)+\frac{1}{2}p\beta_j\big)}\; k^{\operatorname{Re}\psi_t^\star(p)\,-\,1}. \qquad (8.23)
\end{aligned}
$$

Here we set $p=0$ if $\omega(k)=O(1)$.

As in the case ($\star$), there are extra conditions only if $D_0=0$ and $D_0^*=0$. Then we have:

$$
\begin{aligned}
\log|u(N,k)| \;=\; & \sum_{\alpha_j t+\beta_j=0}\alpha_j\;\omega(k)\,\big(\log|\omega(k)|-\log k-1\big) \\
& +k\log g(t)+O(w(k)+\log k). \qquad (8.24)
\end{aligned}
$$

In general, the dominant term is $k\log\,g(t)$; hence we must have $g(t)\le 1$.

Suppose that $g(t_0)=1$ for some $t_0\in\Omega$. If $\Sigma_{\alpha_j t_0+\beta_j=0}\,\alpha_j\neq 0$, then the first term in (8.24) approaches $+\infty$ for those $\omega(k)\sim C_0k^p$ with p close to 1 and with $C_0>0$ or $C_0<0$ depending on the sign of $\Sigma_{\alpha_j t_0+\beta_j=0}\,\alpha_j$. Hence $\Sigma_{\alpha_j t_0+\beta_j=0}\,\alpha_j=0$ for those $t_0\in\Omega$ for which $g(t_0)=1$. Then $\Sigma_{\alpha_j t_0+\beta_j=0}\,\beta_j=0$ as well.

If $\Sigma_{\alpha_j t_0+\beta_j=0}\,\alpha_j=0$, then $g(t)$ is actually differentiable at t_0 by part *(iii)* of Lemma 5.1. The value of the derivative can be derived from (5.6) or (5.8). If $D_0=0$, $D_0^*=0$, $g(t_0)=1$ and $\Sigma_{\alpha_j t_0+\beta_j=0}\,\alpha_j=0$, we can rewrite (8.23) as follows:

$$
|u(N,k)|\sim\exp\left(\omega(k)\,\frac{g'(t_0)}{g(t_0)}\right)\exp\!\left(\omega(k)\,\widetilde{\Phi}_{t_0}\!\left(\frac{\omega(k)}{k}\right)\right)k^{\operatorname{Re}\psi_t^\star(p)\,-\,1}. \qquad (8.25)
$$

If $g'(t_0)\neq 0$, then condition *(e1)* is contradicted for some point $t\in\mathbb{R}\setminus\Omega$ in a neighborhood of t_0. Hence we may assume $g'(t_0)=0$. Eventually we get the following conditions:

(e3) If $D_0=0$, $D_0^*=0$, then $g(t)\le 1$ for all positive $t\in\Omega$.

(e4) If $D_0=0$, $D_0^*=0$, $g(t_0)=1$ for some positive $t_0\in\Omega$, then for any $t_0\in\mathbb{R}\setminus\Omega$ where $g(t_0)=1$ we must have $\sum_{\alpha_j t_0+\beta_j=0}\,\alpha_j=0$, $\operatorname{Re}\psi_{t_0}^\star(0)<0$, and one of the following two conditions satisfied:

(e4A) $\widetilde{\Phi}_{t_0}(x)\equiv 0$, and $\operatorname{Re}\psi_{t_0}^\star(1)\le 0$.

(e4B) $\widetilde{\Phi}_{t_0}(x) = v_m x^m + O(x^{m+1})$ around $x = 0$, where m is a positive odd integer, $v_m < 0$, and $\operatorname{Re}\psi^\star_{t_0}\left(\frac{m}{m+1}\right) < 0$.

The subcases of (*e4*) are derived similarly as the subcases of (*e2*). Compared with conditions *(e1)–(e2)*, we additionally have the condition $\sum_{\alpha_j t_0+\beta_j=0} \alpha_j = 0$ in *(e4)*. But this condition is trivially satisfied in case ($\star$), so formally we may require it in both cases. An implicit difference between cases ($\star$) and ($\star\star$) is that the functions $\psi^\star_t(p)$ and $\widetilde{\Phi}_t(x)$ can be defined simpler in case ($\star$).

Before summarizing up the derived conditions, we remark that the nonzero Taylor coefficients (3.5) of $\Theta(x)$ have the same signs as the Taylor coefficients of the rational function $x/(1+x) = \sum_{j=1}^{\infty}(-1)^{j+1}x^j$. The corresponding coefficients differ the positive factor $j\,(j+1)$. If we replace each occurrence of $\Theta(x)$ by $x/(1+x)$ in definitions (8.7), (8.13), (8.18) of $\widetilde{\Phi}_\infty(x)$, $\widetilde{\Phi}_0(x)$, $\widetilde{\Phi}_\lambda(x)$, respectively, we get the rational functions $\Phi_\infty(x)$, $\Phi_0(x)$, $\Phi_\lambda(x)$ defined in (5.15), (5.14), (5.13), respectively. The Taylor coefficients around $x = 0$ of the rational functions differ by the positive factor $j\,(j+1)$ from the respective coefficients of the corresponding $\widetilde{\Phi}$-functions. Therefore we may replace in conditions *(c5)*, *(d5)*, *(e2)*, *(e4)* the functions $\widetilde{\Phi}_\infty(x)$, $\widetilde{\Phi}_0(x)$, $\widetilde{\Phi}_\lambda(x)$ by the rational functions $\Phi_\infty(x)$, $\Phi_0(x)$, $\Phi_\lambda(x)$, respectively.

Now we summarize the conditions *(a1)–(a3)*, *(b1)–(b7)*, *(c1)–(c5)*, *(d1)–(d5)*, *(e1)–(e4)*. Note that

$$\textit{(a1)} \Rightarrow \textit{(b5)} \;\&\; \textit{(d1)}, \qquad \textit{(a2)} \Rightarrow \textit{(d2)}, \qquad \textit{(b1)} \Rightarrow \textit{(c1)}, \qquad \textit{(b2)} \Rightarrow \textit{(c2)},$$
$$\textit{(c4)} \Rightarrow \textit{(b6)}, \qquad \textit{(a1)} \;\&\; \textit{(b3)} \Rightarrow \textit{(c3)}, \qquad \textit{(a3)} \;\&\; \textit{(b1)} \Rightarrow \textit{(d3)}.$$

Therefore we may discard the conditions *(b5)–(b6)*, *(c1)–(c3)*, *(d1)–(d3)*. Because of *(a3)*, we can drop the restriction $\operatorname{Re} A_0 < 0$ in *(d5)*. Because of *(b3)*, we can drop the restriction $\operatorname{Re} A^*_\infty \le 0$ in *(c5)*. Besides, in cases *(c5A)* and *(c5B)* we can drop condition *(b7)*, because $\operatorname{Re}(A^*_\infty + A^*_0) \le \operatorname{Re} A^*_1$.

We have the following correspondence between the conditions:

$$\textit{(a1)} \;\&\; \textit{(b1)} \Rightarrow \textit{(i)}, \qquad \textit{(a2)}-\textit{(a3)} \Leftrightarrow \textit{(ii)}, \qquad \textit{(b2)}-\textit{(b4)} \Leftrightarrow \textit{(iii)},$$
$$\textit{(e1)} \;\&\; \textit{(e3)} \Leftrightarrow \textit{(iv)}, \qquad \textit{(e2)} \;\&\; \textit{(e4)} \Leftrightarrow \textit{(v)}, \qquad \textit{(d4)}-\textit{(d5)} \Leftrightarrow \textit{(vi)},$$
$$\textit{(c4)}-\textit{(c5)} \;\&\; \textit{(b7)} \Leftrightarrow \textit{(vii)}.$$

The limit $\lim_{n\to\infty}\mathcal{U}(n)$ is discussed right after the conditions *(b1)–(b4)* here above. QED.

9 Properties of $g(t)$

As mentioned in remark *(VI)* after Theorem (6.1), all conditions of Theorem 6.1 can be determined algorithmically. The only less straightforward part is dealing with the function $g(t)$ in parts *(iv)–(v)*. This is significant when $D_0 = 0$ and $D_0^* = 0$. Some key properties of $g(t)$ are presented in Lemma 5.1. Here we focus on finding local extremuma of $g(t)$. At the end, a simplified version (9.4) of this function is considered thoroughly.

Lemma 9.1 *In the context of Sections 4 and 5, suppose that $D_0 = 0$, $D_0^* = 0$, and that conditions (ii)–(iii), (vii) of Theorem 6.1 hold. Then $g(t) \le 1$ for all $t > 0$ if and only if the following conditions hold:*

- *For all $t \notin \Omega$ such that*
$$|\zeta_0| \prod_{\alpha_j \neq 0} \left| t + \frac{\beta_j}{\alpha_j} \right|^{\alpha_j} = 1 \qquad (9.1)$$
we have
$$|z_1| \prod_{\alpha_j \neq 0} \left| t + \frac{\beta_j}{\alpha_j} \right|^{\beta_j} \le 1. \qquad (9.2)$$
- *For all $t \in \Omega$ such that equality (6.2) holds, we have $g(t) \le 1$.*

If these conditions are satisfied, then $g(t) = 1$ are those points $t \notin \Omega$ where equalities in (9.1) and (9.2) hold, and possibly some points $t \in \Omega$ where equality (6.2) holds.

Proof. By parts *(i)–(ii)* of Lemma 5.1, the function $g(t)$ is continuous on $\mathbb{R}$, and it is continuously differentiable on $\mathbb{R} \setminus \Omega$. We need to investigate the behavior of $g(t)$ as t approaches $+\infty$, 0 or singularities of $g'(t)$, and find local extremuma of $g(t)$.

As $t \to 0$, then $g(t) \to |z_0|$ by part *(iv)* of Lemma 5.1. But $|z_0| \le 1$ by part *(ii)* of Theorem 6.1. As $t \to \infty$, then $g(t) \sim |z_1| \exp(D_1) \, |\zeta_0|^t \, t^{D_1}$ by part *(iv)* of Lemma 5.1. The chain of possible restrictions $|\zeta_0| \le 1$, $D_1 \le 0$, $|z_1| \le 1$ is implied by parts *(iii)*, *(vii)* of Theorem 6.1. By part *(iv)* of Lemma 5.1, genuine points of discontinuity of $g'(t)$ are not local extremuma.

It remains to check the local extremuma at those $t > 0$ where $g'(t)$ is actually continuous. For these points, either $t \notin \Omega$, or $t \in \Omega$ and equality (6.2) holds. Condition (9.1) is just reformulation of $g'(t) = 0$, following expression (5.6). Recall that we assume $S = R$. Inequality (9.2) is equivalent to $g(t) \le 1$ if condition (9.1) is satisfied.

If $g(t) \le 1$ for all $t > 0$, then the points with $g(t) = 1$ are local extremuma. If $t \in \Omega$ and $g'(t) = 0$, then the quotient of the left and right hand sides of (9.2) is equal to $g(t)$. QED.

Here we continue the list of observations *(I)–(IX)* in Section 6 with a few more remarks.

(X) If all α_j's and γ_j's are even, then condition (9.1) is actually a polynomial equation for t. If there are some odd α_j's or γ_j's, we can square both sides of (9.1) and get a polynomial equation for t as well. We have to find real positive roots of these equations. The numeric or algebraic roots of the polynomial equations can be found algorithmically. On the other hand, the equations might have inappropriately high degree. It might be useful to have some estimates of the number and location of relevant solutions.

(XI) The two conditions for $g(t) \le 1$ can be formulated in a single statement, if we add the condition $\alpha_j t + \beta_j \neq 0$ to the products in (9.1) and (9.2), or make the convention that the both-side factors $|t-\lambda|$ with $\lambda = t$ in these formulas cancel out if $t \in \Omega$ and equality (6.2) holds. The unified statement is: For all $t > 0$ such that equalities (6.2) and (9.1) hold, we must have (9.2). Identification of the points $g(t) = 1$ in Lemma 9.1 can be similarly unified. From algorithmic point of view, the single equation (9.1) with simplified or cancelled-out powers of $|t-\lambda|$ determines all local extremuma.

(XII) Let us denote $h(t) = g'(t)/g(t)$. Using formula (5.5) we derive

$$h'(t) = \sum \frac{\alpha_j^2}{\alpha_j t + \beta_j}. \tag{9.3}$$

If we compute the zeroes and poles of this rational function, and (signs of) values of $h(t)$ there, we can determine intervals where zeroes of $h(t)$ lie. Since $g'(t)$ has the same sign as $h(t)$ for any $t \notin \Omega$, those are also intervals for the zeroes of $g'(t)$, or extremuma of $g(t)$.

(XIII) Lemma 9.1 formally holds in the case when $g(t)$ is a constant function as well. Of course, in that case condition *(iv)* of Theorem 6.1 is straightforward to handle.

(XIV) The second paragraph in the proof of Lemma 9.1 shows that part *(iv)* of Theorem 6.1 implies $|z_1| \le 1$ if $|\zeta_0| = 1$, $D_1 = 0$ (and $D_0^* = 0$). Consequently, one may simplify part *(vii)* of Theorem 6.1 by starting "*If* $|\zeta_0| = 1$, $D_1 = 0$ *and* $|z_1| = 1$, *then ...*", and dropping all further conditions on z_1. Similarly, because of the asymptotics in (5.11), part *(iv)* of Theorem 6.1 implies $|\zeta_1| \le 1$ if $|z_0| = 1$, $D_1^* = 0$ (and $D_0^* = 0$). Hence, part *(vi)* of Theorem 6.1 can be simplified by starting "*If* $|z_0| = 1$, $D_1^* = 0$ *and* $|\zeta_1| = 1$, *then ...*", and dropping all further conditions on ζ_1. But from computational point of view, it is convenient to use formulation of Theorem 6.1 so to handle the behavior of $g(t)$ as $t \to 0$ and $t \to \infty$ automatically.

In the rest of this Section, we explicitly consider a simple case of the $g(t)$-function:

$$\widehat{g}(t) = \frac{|\alpha\,t+1|^{\alpha t+1}\;|\gamma\,t|^{\gamma t}}{|\alpha\,t|^{\alpha\,t}\;|\gamma\,t+1|^{\gamma t+1}}, \tag{9.4}$$

This case naturally occurs with sequences of hypergeometric functions of the form

$$ {}_s\mathrm{F}_r\left(\begin{array}{c} a_1+\alpha\,n,\; a_2,\;\ldots,\; a_s \\ c_1+\gamma\,n,\; c_2,\;\ldots,\; c_r \end{array} \middle|\; z \right). \tag{9.5}$$

There may be more upper and lower parameters dependant on n, if they cancel each other out in the expression of $g(t)$. We saw the same function in Example 7.1; see (7.4). Knowledge of the function $\widehat{g}(t)$ may help to arrive at effective estimates for more complicated functions $g(t)$, by splitting them into a product of $\widehat{g}(t)$'s.

In the following Lemma, we present basic properties of $\widehat{g}(t)$. We assume here that $\gamma>0$, but allow t to be both positive and negative. If $\gamma<0$ in (9.4), then Lemma 9.2 can be applied by considering $\gamma\mapsto-\gamma$, $t\mapsto -t$, $\alpha\mapsto-\alpha$, so that $\gamma>0$ and $t<0$.

Lemma 9.2 *Assume that α, γ are integers, $\alpha\neq\gamma$ and $\gamma>0$.*

(i) The function $\widehat{g}(t)$ is continuous on the whole real axis, and is differentiable everywhere except the points $x\in\{0,-1/\alpha,-1/\gamma\}$. These three points are not local extremuma.

(ii) $\widehat{g}(0)=1$, and $\lim_{t\to\pm\infty}\widehat{g}(t)=|\alpha/\gamma|$.

(iii) $\sup_{t>0}\widehat{g}(t)=\max(1,|\alpha/\gamma|)$.

(iv) The global supremum of $\widehat{g}(t)$ is achieved for a negative t, and it is the only local extrema which satisfies $\widehat{g}(t)>1$ and $\widehat{g}(t)>|\alpha/\gamma|$.

Proof. The first part follows from parts *(i)–(iii)* of Lemma 5.1. The value $\widehat{g}(0)$ is trivial. We have

$$\lim_{t\to\infty}\widehat{g}(t)=\lim_{t\to\infty}\frac{|\alpha\,t+1|}{|\gamma\,t+1|}\left|1+\frac{1}{\alpha\,t}\right|^{\alpha\,t}\Big/\left|1+\frac{1}{\gamma\,t}\right|^{\gamma\,t}=\left|\frac{\alpha}{\gamma}\right|,$$

and similarly for $\lim_{t\to-\infty}\widehat{g}(t)$.

Let us consider

$$h(t):=\frac{\widehat{g}\,'(t)}{\widehat{g}(t)}=\alpha\,\log|1+\alpha\,t|-\alpha\,\log|\alpha\,t|+\gamma\,\log|\gamma\,t|-\gamma\,\log|1+\gamma\,t|. \tag{9.6}$$

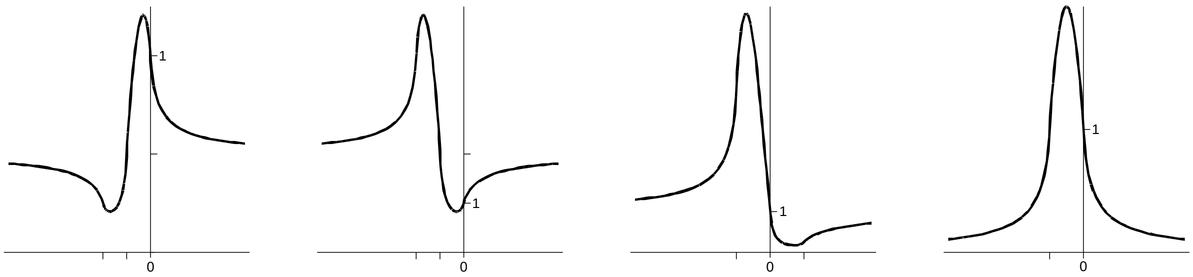

Figure 1: The function $\widehat{g}(t)$ for various α/γ

The local extremuma of $\widehat{g}(t)$ are determined by $h(t)=0$. We have:

$$h'(t) = \frac{\gamma-\alpha}{t\,(1+\alpha\,t)\,(1+\gamma\,t)}, \tag{9.7}$$

We conclude that $h(t)$ and $\widehat{g}'(t)$ are monotone on the intervals separated by points 0, $-1/\alpha$ and $-1/\gamma$. Here are some relevant limits:

$$\lim_{t\to-1/\gamma} h(t) = \infty, \qquad \lim_{t\to\pm\infty} h(t) = 0,$$

$$\lim_{t\to-1/\alpha} h(t) = \begin{cases} -\infty, & \text{if } \alpha > 0, \\ \infty, & \text{if } \alpha < 0. \end{cases} \qquad \lim_{t\to 0} h(t) = \begin{cases} \infty, & \text{if } \alpha > \gamma, \\ -\infty, & \text{if } \gamma > \alpha. \end{cases}$$

We distinguish the following cases:

- If $0<\alpha<\gamma$, then $\widehat{g}(t)$ has a local maximum on the interval $(-1/\gamma, 0)$, which is greater than $\widehat{g}(0)=1>\alpha/\gamma$. There is a local minimum on $(-1/\alpha,-1/\gamma)$, which is less than $\widehat{g}(-\infty)=\alpha/\gamma<1$. For positive t, the function $\widehat{g}(t)$ decreases from 1 to α/γ. See the first graph in Figure 1.

- If $0<\gamma<\alpha$, then $\widehat{g}(t)$ has a local maximum on the interval $(-1/\gamma,-1/\alpha)$, which is greater than $\widehat{g}(-\infty)=\alpha/\gamma>1$. There is a local minimum on $(-1/\alpha, 0)$, which is less than $\widehat{g}(0)=1<\alpha/\gamma$. For positive t, function $\widehat{g}(t)$ increases from 1 to α/γ. See the second graph in Figure 1.

- If $\alpha<0$, then $\widehat{g}(t)$ has a local maximum on the interval $(-1/\gamma, 0)$, which is greater than $\widehat{g}(-\infty)=|\alpha/\gamma|$ and $\widehat{g}(0)=1$. There is a local minimum on $(0,-1/\alpha)$, which is less than 1 and $|\alpha/\gamma|$. The supremum of $\widehat{g}(t)$ over positive t is achieved as $t\to 0$ or $t\to\infty$. See the third graph in Figure 1.

- If $\alpha = 0$, then $g(t)$ has a local maximum on the interval $(-1/\gamma, 0)$, which is greater than $\widehat{g}(0) = 1$. There are no other extremuma in this case. For positive t, the function $\widehat{g}(t)$ decreases from 1 to 0. See the last graph in Figure 1.

This analysis proves parts *(iii)–(iv)* of the Lemma. QED.

Corollary 9.3 *Suppose that $\alpha \neq \gamma$. If $\gamma > 0$, then the supremum of $\widehat{g}(t)$ over $t > 0$ is achieved either as $t \to 0$ or $t \to \infty$. If $\gamma < 0$, then the supremum of $\widehat{g}(t)$ over $t > 0$ is achieved for some $t \in \left(0, \frac{1}{|\gamma|}\right)$.*

Proof. If $\gamma > 0$, we use parts *(ii)–(iii)* of Lemma 9.2. If $\gamma < 0$ then we apply Lemma 9.2 after changing the signs $\gamma \mapsto -\gamma$, $t \mapsto -t$, $\alpha \mapsto -\alpha$. QED.

To estimate how high is the maximum of $\widehat{g}(t)$ over those t with $\gamma\, t < 0$, we need this Lemma.

Lemma 9.4 *Suppose that $x \geq 1$. The equation*

$$\frac{y^x}{x^x} = \frac{(y+1)^{x-1}}{(x-1)^{x-1}} \tag{9.8}$$

has a unique root y such that $y \geq 1$.

Let $y(x)$ denote the unique root as a function of x. Asymptotically,

$$y(x) \sim \tau\, x - \frac{\tau+1}{2} - \frac{(\tau+1)\,(\tau-2)}{24\,\tau}\,\frac{1}{x} + \ldots, \qquad \text{as } x \to \infty, \tag{9.9}$$

where τ is the real solution of $\log(\tau) = 1 + 1/\tau$*:*

$$\tau \approx 3.5911214766686221366492229257416348421 0\ldots. \tag{9.10}$$

For $x \geq 1$ we have

$$\tau\,(x-1) + 1 < y(x) < \tau\,(x-1) + \frac{\tau-1}{2}. \tag{9.11}$$

Proof. Let us consider the logarithm of the ratio of both sides of (9.8):

$$\Psi(x,y) = x\,\log y - x\,\log x - (x-1)\,\log(y+1) + (x-1)\,\log(x-1). \tag{9.12}$$

For fixed $x \geq 1$, we have to find solutions of $\Psi(x,y) = 0$ with $y \geq 1$. We have:

$$\frac{\partial\Psi(x,y)}{\partial y} = \frac{y+x}{y(y+1)}. \tag{9.13}$$

Hence, as a function of y, $\Psi(x,y)$ is continuous increasing function on the interval $(1,\infty)$. There can be at most one root $y \ge 1$. We may check

$$\begin{aligned} \Psi(x,1) &= (x-1)\log\frac{x-1}{2} - x\log x, & (9.14)\\ \Psi(x,y) &\sim \log y + O(1) \quad \text{as } y \to \infty. & (9.15) \end{aligned}$$

Since $\Psi(x,1) < 0$, and $\Psi(x,y) \to \infty$ as $t \to \infty$, there exists a root $y \ge 1$ indeed.

A straightforward attempt to solve $\Psi(x,y) = 0$ asymptotically gives (9.9).

To prove the inequalities in (9.11), we show

$$\Psi\big(x, \tau\,(x-1)+1\big) < 0, \qquad \Psi\left(x, \tau\,(x-1) + \frac{\tau-1}{2}\right) > 0. \tag{9.16}$$

Then the monotonicity of $y(x)$ will imply (9.11).

First we show the second inequality. We substitute $y = \tau\,x - (\tau+1)/2$ into $\Psi(x,y)$:

$$\begin{aligned} \Psi(x,y) &= \log(\tau) + x\,\log\left(1 - \frac{\tau+1}{2\,\tau\,x}\right) - (x-1)\,\log\left(\frac{x}{x-1}\left(1-\frac{\tau-1}{2\,\tau\,x}\right)\right)\\ &= \sum_{j=1}^{\infty} \frac{1}{j\,(j+1)}\left(1 - j\left(\frac{\tau+1}{2\,\tau}\right)^{j+1} - \frac{\tau\,j+j+2\,\tau}{2\,\tau}\left(\frac{\tau-1}{2\,\tau}\right)^{j}\right)\frac{1}{x^j}. \quad (9.17) \end{aligned}$$

The power series converges for $x > 1$, since a tail of it can be majorated by $\sum_j \frac{1}{j\,(j+1)}\,x^{-j}$. The series terms are positive for large enough j. The first terms of (9.17) are

$$\frac{0.03017\ldots}{x^2} + \frac{0.03017\ldots}{x^3} + \frac{0.02564\ldots}{x^4} + \ldots$$

After applying Lemma 3.7 twice with $p = (\tau \pm 1)/2\tau$, we conclude that all terms in the series are positive. Hence the second inequality in (9.16) follows.

If $y = \tau\,x - \tau + 1$, then

$$\begin{aligned} \Psi(x,y) &= \log(\tau) + x\,\log\left(1 - \frac{\tau-1}{\tau\,x}\right) - (x-1)\,\log\left(\frac{x}{x-1}\left(1-\frac{\tau-2}{\tau\,x}\right)\right)\\ &= \sum_{j=1}^{\infty} \frac{1}{j\,(j+1)}\left(1 - j\left(\frac{\tau-1}{\tau}\right)^{j+1} - \frac{2\,j+\tau}{\tau}\left(\frac{\tau-2}{\tau}\right)^{j}\right)\frac{1}{x^j}. \quad (9.18) \end{aligned}$$

The power series converges for $x > 1$, just as (9.17). The series terms are positive for large enough j. The first terms of (9.18) are

$$-\frac{0.10522\ldots}{x} - \frac{0.02770\ldots}{x^2} - \frac{0.00378\ldots}{x^3} + \frac{0.00466\ldots}{x^4} + \ldots$$

Applying lemma 3.7 twice with $p = (\tau - 1)/\tau$ and $p = (\tau - 2)/\tau$ we conclude that starting with the power x^{-4} the coefficients are positive. Hence the first three terms in (9.18) are negative, and all remaining terms in (9.18) are positive. Let us consider the function

$$\Psi_1(x) = x^3\,\Psi(x,\ -\tau\,x + \tau + 1). \tag{9.19}$$

The Laurent series of the derivative of this function at $x = \infty$ is:

$$\frac{d\,\Psi_1(x)}{dx} = -0.21044\ldots x - 0.02770\ldots - \frac{0.00466\ldots}{x^2} + \ldots$$

The information about the signs of the coefficients in (9.18) implies that all nonzero terms in the Laurent series are negative. Therefore $\Psi_1(x)$ is a decreasing function on the interval $(1, \infty)$. Further, $\lim_{x\to 1^+} \Psi_1(x) = 0$, since $\Psi(x, y)$ is continuous and $\Psi(1, 1) = 0$. Therefore $\Psi_1(x) < 0$ for $x \in (1, \infty)$. Consequently, the first inequality in (9.16) follows as well. QED.

The main result about the function $\widehat{g}(t)$ defined in (9.4) is the following.

Theorem 9.5 *Suppose that α, γ are integers. Then*

$$\sup_{t>0} \widehat{g}(t) = \begin{cases} 1, & \text{if } \alpha = \gamma, \\ \infty, & \text{if } \gamma = 0,\ \alpha \neq 0, \\ \max(|\frac{\alpha}{\gamma}|, 1), & \text{if } \gamma > 0, \\ y(\frac{\alpha}{\gamma}), & \text{if } \alpha < \gamma < 0, \\ 1 + 1/y(\frac{\gamma}{\gamma-\alpha}), & \text{if } \gamma < \alpha < 0, \\ 2, & \text{if } \gamma < 0,\ \alpha = 0, \\ 1 + y(\frac{\gamma-\alpha}{\gamma}), & \text{if } \gamma < 0 < \alpha. \end{cases} \tag{9.20}$$

where the function $y(x)$ is defined in Lemma 9.4.

Proof. If $\alpha = \gamma$, then $\widehat{g}(t) \equiv 1$. If $\gamma \neq 0$, then

$$\widehat{g}(t) = \left|1 + \frac{1}{\alpha\,t}\right|^{\alpha\,t} |\alpha\,t + 1|,$$

and $\widehat{g}(t) \sim \exp(1)\,|\alpha|\,t$ as $t \to \infty$. If $\gamma > 0$, we apply part *(iii)* of Lemma 9.2.

From now on we assume $\gamma < 0$, $\alpha \neq \gamma$. We use Lemma 9.2 with the flipped signs of γ, t and α. By part *(iv)*, the supremum is a local extremum, so it is achieved for some $t = t_{\text{sup}}$ (dependent on α and γ) satisfying $\widehat{g}\,'(t_{\text{sup}}) = 0$. Expression (9.6) gives the following equation for t_{sup}:

$$\frac{|\alpha\,t_{\text{sup}} + 1|^{\alpha}\ |\gamma\,t_{\text{sup}}|^{\gamma}}{|\alpha\,t_{\text{sup}}|^{\alpha}\ |\gamma\,t_{\text{sup}} + 1|^{\gamma}} = 1. \tag{9.21}$$

Hence,

$$\widehat{g}(t_{\rm sup}) = \frac{|\alpha\, t_{\rm sup}+1|}{|\gamma\, t_{\rm sup}+1|}. \tag{9.22}$$

Let us define the function

$$\widetilde{y}(\alpha,\gamma) = \frac{\alpha\, t_{\rm sup}+1}{\gamma\, t_{\rm sup}+1}, \tag{9.23}$$

so that $\widehat{g}(t_{\rm sup}) = |\widetilde{y}(\alpha,\gamma)|$. We have:

$$\begin{aligned} \frac{|\widetilde{y}(\alpha,\gamma)|^{\alpha}}{|\widetilde{y}(\alpha,\gamma)-1|^{\alpha-\gamma}} &= \frac{|\alpha\, t_{\rm sup}+1|^{\alpha}\;|t_{\rm sup}|^{\gamma-\alpha}}{|\gamma\, t_{\rm sup}+1|^{\gamma}\;|\alpha-\gamma|^{\alpha-\gamma}} \\ &= \frac{|\alpha|^{\alpha}}{|\gamma|^{\gamma}\;|\alpha-\gamma|^{\alpha-\gamma}}, \end{aligned} \tag{9.24}$$

where the second equality holds because of (9.21). Formula (9.24) implies that $\widetilde{y}(\alpha,\gamma)$ is a real solution of

$$\frac{|\widetilde{y}|^{x}}{|x|^{x}} = \frac{|\widetilde{y}-1|^{x-1}}{|x-1|^{x-1}}, \qquad \text{where} \quad x=\frac{\alpha}{\gamma}, \quad \widetilde{y}=\widetilde{y}(\alpha,\gamma) \tag{9.25}$$

Conversely, if (9.25) holds, then expression (9.23) is also true provided that $t_{\rm sup}$ is well defined, which is not the case only when $\widetilde{y}(\alpha,\gamma)=\alpha/\gamma$. It follows that all solutions of (9.25) except $\widetilde{y}=x$ correspond to local extremuma of $\widehat{g}(t)$. We need a solution of (9.25) whose absolute value is greater than $\max(1,|x|)$.

The cases $x=1$ and $x=0$ can be proved by solving the equation (9.25) directly.

If $x>1$, we have two possibilities: either $\widetilde{y}>1$ or $\widetilde{y}<-1$ for the relevant solution of (9.25). But if $\widetilde{y}>0$ and $\widetilde{y}>x$, then the left-hand side of (9.25) is always bigger than the right-hand side. Hence the relevant solution has $\widetilde{y}<-1$. Then $y=|\widetilde{y}|$ satisfies (9.8), so the supremum for $\alpha<\gamma<0$ is equal to $y\,(\alpha/\gamma)$.

If $x<0$ then the transformation $x\mapsto 1-x$, $\widetilde{y}\mapsto 1-\widetilde{y}$ transforms equation (9.25) to the same equation with $x>1$. Since $\widetilde{y}=-y\,(\alpha/\gamma)$ for $x>1$, we get the result for $\gamma<0<\alpha$.

Similarly, if $x\in(0,1)$ then the transformation $x\mapsto 1/(1-x)$, $\widetilde{y}\mapsto 1/(1-\widetilde{y})$ transforms equation (9.25) to the same equation with $x>1$. The inverse transformation on $\widetilde{y}$ for $x>1$ is $1-1/\widetilde{y}$, with $\widetilde{y}=-y\,(\alpha/\gamma)$ again. Hence the remaining case $\gamma<\alpha<0$ follows. QED.

Figure 2 gives the graph of $\sup_{t>0}\widehat{g}(t)$ for $\lambda<0$ as a function of α/γ, as specified by Theorem 9.5. The continuous graph is piecewise defined on the intervals $(-\infty,0)$, $(0,1)$ and $(1,\infty)$. On the interval $(1,\infty)$, the function is identical to the function $y(x)$ of Lemma 9.4. The thin lines above the interval $[1,\infty)$ are the bounding lines in (9.11). As we see, the

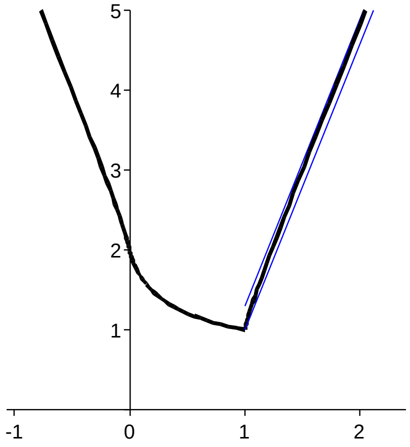

Figure 2: The supremum of $\widehat{g}(t)$ for $\gamma\, t < 0$, as a function of $\dfrac{\alpha}{\gamma}$.

function approaches the asymptotic straight line very fast. The function can be transformed between the three intervals by the fractional-linear transformations implied in Theorem 9.5. The tangent slopes at $\alpha/\gamma = 1$ (from the right) and at $\alpha/\gamma = 0$ (from both sides) are actually vertical. To see this at $\alpha/\gamma = 1$, compute dy/dx from $\Psi(x, y) = 0$ as in (9.12). The tangent slope at $\alpha/\gamma = 1$ from the left is equal to $-1/\tau$.

As we see, the graph in Figure 2 grows rather fast with $|\alpha/\gamma|$. If one tries to estimate the supremum of $g(t)$ by expressing it as a product of $\widehat{g}(t)$'s, the negative γ_j's should be preferably paired with negative α_j's of similar magnitude, so that the respective quotients α/γ would be close to 1.
